TONITED STATES DEMARTER TO OF AGRICULTURE

GROP REPORT as of December 1, 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

GENERAL CROP REPORT, AS OF DECEMBER 1, 1943

The favoring conditions that resulted in outstanding crop production in 1948 continued well into November in most areas. Harvest of late-growing crops is mostly ahead of schedule and other farm work is well advanced, especially fall plowing. lains early in the month and mild temperatures fostered development of winter wheat. so that even the late-seeded portion will face the winter with good chemics of currival. Most dry areas have received relief. In a large southeastern area, excessive cains and floods interfered with cotton picking and completion of harvest of other crops, with some loss resulting. Completion of seeding of fall grains also was delayed.

Official Department of Agriculture estimates of winter wheat and rya acreages sown for hervest in 19^{l_1} 9, with a forecast of wheat production, will be issued on December 20. In many sections, seeding was continued into November. In the eastern Corn Belt, seeding followed late completion of soybean harvest and in the central and southern Growt Plains seeding was made feasible by good rains the first for days of the month. Good growing weather continued throughout November, improving stands in spotted fields, permitting replanting where grasshoppers had caused damage along borders of fields, and resulting in good root development that promises to survive usual vinter conditions. Wet fields in parts of the Southeast have thus far prevented completion of seeding of the intended acreage. In the Pacific Northwest, conditions for seeding and growth were about as usual, but frozen ground and snow in Washington had checked growth at the end of November. Preparation of fields and reading of wheat continues in Texas and California, where dryness has deleved operations. Some wheat pasture was available in Kansas, but little elsewhere.

Both precipitation and temperatures were about normal in most of the eastern half of the country during November, but below normal in much of the western half. The mild weather and ample moisture were beneficial in the Forth Central and Great Plains States. But in the Southeast, rainfall ranged from twice normal to as much as 6 times normal in parts of Georgia and Alabama, resulting in yet and flooded fields and some crop loss. The dampness in the Corn Belt slowed curing of corn left in fields and in some cases caused moldiness in stored corn. Shortage of rainfall in eastern parts of Wyoming and Montana left wheat in only poor to fair condition. Rainfall also was short in the area from Texas and Oklahoma (except the Pannandles) westward across New Mexico, Arizona, southern Utah, Nevada and California, continuing the poor crop conditions that have preveiled in that exec. In northern mountain areas and Washington, freezing temperatures and snow ended the growing season, but work was well advanced and harvest completed. The blizzard that struck western Kansas the third week in November and swept across Nebrocke, leaving snow in drifts, moved on into South Dakota, Minnesota and northern parts of Wisconsin and Michigan. Few other sections had snow on December 1.

Production of milk and eggs prospered with the mild Hovember weather and heavy feeding rates. Milk production per cow topped any previous cut mit in Nevember, but numbers of milk cows on farms were the smallest for the month since 1930. Total milk production in November exceeded that of last year, but was less than in 5 of the past 7 years. Pastures were furnishing some grazing, but with ample supplies of corn and other feeds cattle were fed more liberally than ever before rejorted. Egg production in November set a new record for the month, not only in eggs per hen, but also in total eggs produced. Production in the first 11 months of 1940 about equalled that in the same period of 1947. The total laying flock in Fovember was percent less than a year ago, but 5 percent above average. As prices of feed decreased more rapidly than prices of eggs and chickens, feeding ratios were relatively favorable.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 10, 1948 December 1, 1948 3:00 P.H. (D.S.T.)

CITRUS: Early and midseason oranges for the 1948-49 crop are estimated at 53.3 million boxes -- 1 percent less than last season, but 29 percent more than average. How crop Valencia oranges are forecast at 61.6 million boxes -- 9 percent above last season and 28 percent above average. The grapefruit crop is now indicated at 56.2 million boxes, compared with 61.6 million boxes in 1947-48 and 47.5 million boxes average. Colifornia lemons are forecast at 13.1 million boxes, cornered with 12.9 million boxes last season and 12.8 million boxes average.

In Florida, most of November was, dry in the citrus areas, but some rain fell the latter part of November and early December. Temperatures have been above normel. Early and midseason oranges are estimated at 34 million boxes -- 3 million more than last scason and 14 million more than average. Valencias are forecast at 30 million boxes, compared with 27.4 million boxes last season and 16.5 million boxes everage. Grapefruit are placed at 31 million boxes - 2 million less than last season, but 7 million more than average. Tangerines are estimated at 4 million boites, the same as in 1947-48 and 19 percent above average. Volume of fruit harvested has been greater this season than last. By November 27, a little over 7.5 million boxes of oranges, 5.5 million boxes of grayefruit and 1.3 million boxes of tangerines had been harvested. This compares with 5.5 million boxes of oranges, belimillion boxes of granefruit and 431,000 homes of tangerines harvested by the same date last year.

Conditions in the Lower Valley of Texas were very satisfactory through most of November. While rainfall for the north was light and accumulation for the season is considerably below normal, fall rains were timely and fruit sized well with quality good. Temperatures fell below freezing on Movember 30. Practically no damage was caused by the cold, but strong winds for two days resulted in considerable defoliation of trees. Oranges are forecast at 4.7 million bottes -- 10 percent less than last season, but 45 percent above average. Harly and midsoaron varieties are forecast at 2.9 million hoxes. Texas grapefruit are estimated at 19 million boxes - 18 percent less than last season, but 9 percent above average. Hovement of oranges to December 1 was 37 percent more than last year to the same date and movement of grapefruit was 15 percent more. Rail-movement has been lighte than last year, but truck shipments about double. Movement of Texas lemons to date is only about one-third as heavy as last year. Supplies have been plentiful since November 1, but the demand has not been strong. The crop from the late bloom continues to note good progress and later senson yields should be good.

<u>Louising</u> oronges are forecast at 320,000 boxes, compared with last season's production of 300,000 boxes and the 10 year average of 298,000 boxes.

Arisona citrus has experienced many frosty mornings, but apparently has suffered no damage as yet. Moisture sumplies continue critically short. Granefruit are estimated at 3.6 million boxes -- 20 percent above last season and 9 percent above average. Oranges are forecast at 1.2 million boxes -- 51 percent above 1947-48 and 48 percent above average. Navels and miscellaneous are forecast at 580,000 homes and Valencias at 500,000 boxes. Lemon prospects are poor. Trees are generally in boor condition and the set is light except on a very few groves which escaped front damage last winter. Quality of the short crop will be good.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 10, 1948 December 15: 1948

and 7 percent below average.

California is still exceedingly dry. A number of frosty nights have apparently caused no damage to citrus. Several days of dry winds have been detrimental to both citrus trees and fruit. Sizes of navel oranges are very small in all areas. The crop of navel and miscellaneous varieties is now estimated at 15.5 million boxes - 18 percent less than the 1947-48 crop and 18 percent less than average. The Valencia crop is forecast at 29.2 million boxes - 9 percent above last season, but 3 percent below average. Sizes are very small again this season. California Desert Valleys grapefruit are estimated at 1.15 million boxes -- 20 percent above last season, but slightly less than average. Harvest of this crop has storted. Summer grapefruit are forecast at 1.5 million boxes - about the same as last season

MILE PRODUCTION: In Movember, for the first time this year, monthly milk production on United States farms exceeded that for the corresponding month of 1947. Mill: production per cov, favored by mild ventuer in the more important dairy areas and a record high level of grain feeding, emcooded the 1946 previous high for Movember by nearly 4 percent. Tumbers of mill cours on farms, however, were the smallest for the month since 1930. Total mill: production in November is estimated at 8,048 million bounds, slightly higher than last year, but lower than in five of the past seven years. Milk production per capita in Toyomber, at 1.82 nounds per day, was the second lowest for the month in records dating from 1930.

Mill: production per cow reached its seasonal low point about December 1 but was at a record high level for that time of the year. The decline from Hovember 1 to December 1 this year was considerably less than usual and contrasted with a nearrecord drop for that period a year ago. In herds kent by crop correspondents, milk production per cow on Pecember 1 this year averaged 13.64 pounds, compared with 12.79 pounds in 1947 and an average of 12,24 pounds for the date in the 1937-46 period. Milk production per cow was relatively high in all parts of the country. Regionally, December & rates ranged from 7 percent above average in the Western group of States to 13 percent above average in the East North Central area. Milk production per cow in all six major geographic divisions was higher than on the same date a year ago,

In the West North Central States, milk production per cor, as usual, passed the seasonal low point about November 1 and by the first of December had increased appreciably. In the East North Central States, the low point for the year was apparently reached earlier than usual with milk per cow on December 1, the normal seasonal low, slightly above that on Movember 1. In the South, production per cov dropped about as usual from November 1 to December 1 and is expected to continue its normal seasonal decline beyond the turn of the year. In the West, the decline from November 1 to December 1 was sharper than usual due in part to cold weather.

In crop correspondent's hords, the percentage of milk cove reported in production declined about as usual and on December 1 averaged 67.1 percent for the country as a whole. This was higher than on the same date in any of the last six years, but about the same as average for the date in the 1937-46 period. The percentage of cows milked in the North Atlantic and Central regions was somewhat below average, but in the South Atlantic and Western areas slightly above average.

In four States - Pennsylvania, Ohio, Virginia, and Morth Carolina -November milk production on farms this year established a new high record for the month. In New Jersey and Wisconsin, this year's November production has been

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 10, 1948 December 1, 1948 3:00 P.M. (E.S.T.) 3:00 P.M. (E.S.T.)

exceeded in only one year during the period for which records are available, and in Tennessee was exceeded in only two years. Monthly estimates are available for a period of 16 to 20 years in these States. Milk production per cow was uniformly high in the 23 States for which monthly estimates are available. In 17 of the States, this year's rate for November equalled, or exceeded, previous record highs. Milk cow numbers, however, were rather generally on the deckine and in some central and western States had reached the lowest point in many years. As a result of the reduced numbers of milk cows, milk production on farms in North Dakota, Kansas, Montana, and Oregon were the lowest for the month in 17 years or more, despite record or near record high milk production per cow. Estimates of monthly milk production on farms in the 23 States for which data are available are shown in the table below.

CROP REPORT as of December 1, 1948 -3:00 P.M.

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 10, 1948 -3:00 P.M. (E.S.T.

GRAIN AND CONCENTRATES FED TO MILK COWS: The feeding of grain and other concentrates to milk cows was at a record rate per cow on December 1. Crop correspondents reported an average of 5.39 pounds fed per cow, which was more than half a pound above the 4.80 pounds reported for Docember 1, 1947. and was also well above the 4.98 pounds fed on December 1, 1946, the highest previously reported rate per cow in the series of Docember 1 records going back through 1933. The 1937-46 average rate per caw was 4.56 pounds.

Mild and open weather conditions prevailed over most of the country on December 1; this would ordinarily tend to reduce the amount of grain fed. However, an abundant supply of home-grown grains, more favorable milk-feed and butterfatfood price ratios than a year ago, and an increased percentage of high producing cows in hords as a result of several years of close culling, have all been factors in raising the breeding rate to its record level.

Heavy feeding of concentrates to dairy cows on December 1 was general in all areas. In every major group of States, the average per cow was above last year and in all regions equalled or exceeded the highest for the date in 16 years of record. Regionally, reports show that, as usual, milk cows in the North Atlantic States were being fed the largest amount per cow -- 6.7 pounds. In the East North Central States, an average of 6.2 pounds was reported; in the West North Central group, 5.5 pounds; in the South Atlantic States, 4.7 pounds; and in the Western States, 4.4 pounds. The lowest feeding rate for any region was 4.0 pounds per cow in the South Central States.

The average value per 100 pounds of the concentrate rations fed to milk cows in November was about one-fifth loss than a year ago and a few cents lower than in November 1946, but higher than in any other year on record beginning with 1910. The value per 100 pounds of rations fed in the country as a whole averaged \$3.20 for November. In milk-selling areas, it was \$3.30, and in cream-selling areas, \$2.83. With feed costs down and wholesale milk prices slightly higher than in November 1947, the milk-feed price ratio was up sharply. At 1.48, the November 1948 milk-feed price ratio was well above the low figure of 1.16 last year and slightly above the 20-year (1927-46) average November ratio of 1.42. The butterfat-feed price ratio was 22.7 this November, higher than the 20.3 a year ago but well below the 20-year average of 26.7.

COMPOSITION OF COMCENTRATE RATIONS FED TO MILK COMS: Corn continues to be the most important single feed in the

fall concentrate ration fed to milk cows, according to reports from nearly 5,000 special dairy reporters. With new corn from this year's bumper crop already being fed on November 1, corn comprised 28.5 percent of the total amount of grain, millfeods and concentrates fed to milk cows in dairy reporters! herds on that date this year. Commercial mixed feed made up 25.7 percent of the total and oats 24.6 percent. These three kinds of feed together account for nearly four-fifths of all grain and concentrates fed to milk cows. The balance of the concentrate ration included barley, 4 percent; wheat millfeeds, 4 percent; wheat, 2 percent; cottonseed meal, 2 percent; linseed meal, 2 percent; soybean or soybean meal, 2 percent; and miscellaneous, 5 percent. Data on each seed as percentage of the fall-fed concentrate ration from 1931 to date are shown in the accompanying table.

Changes from a year ago in percentages of feeds used have not been great and have consisted principally of an increase of 14 percentage points for

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 10, 11948 Pecceber 12-1948

corn and & point for linesed meal, with offsetting decreases of 1 point for commercial mixed feed, and about & point each for oats and barley. In comparison with averages for the 1937-46 period, the most marked increase was in commercial mixed feed - from Ale Percent to 25.7 percent. Percentages of corn and cats on Tovember 1, 1948 were slightly above average, but the percentages of barlay, wheat, and wheat millfeeds were well below average. In the oil seeds and oil-seed meal group, the percentage of linseed meal was above average, but cottonseed, cottonseed meal, and saybeans and soybean meal showed lower percentages.

In the period of years for which reports on the composition of concentrate rations fed to milt cows are available (1931 to date), there has been considerable variation in the relative amounts of the various kinds of feed used. Most of these variations have been terrorary adjustments to the supply situation, but for some feeds there have been changes to entirely different levels. Commercial mixed feeds have increased from an average of about 15 percent of the total for the first five years of the series to an average of nearly 26 percent for the past five years. On the other hand, barley used in farm mired dairy rations had decreased from around 9 percent of the ration fed to less than 5 percent, Wheat and wheat feeds decreased from about 14 percent in the early thirties to about 6 percent in recent years, probably reflecting in part the use of wheat millfeeds for commercia cially mixed dairy feeds and the purchase by farmers of the mixed feed rather than bran or shorts

By regions, the kinds of concentrates fed to dairy cows differed sharply, with this year's feeding following fairly closely, the usual nattern. Commercial mixed feeds made up nearly two-thirds of all concentrates fed in the North Atlantic region and nearly half in the South Atlantic States, Corn and oats were most important in the North Central States with corn accounting for a larger percentage of the total than last year. In the South Central States, cottonseed meal was relatively more important than in other regions, but corn and commercial mixed were the leading kinds of dairy feeds. This year the percentage of oats in the ration in this area was less then usual as a result of the short crop in Oblahóma and Texas. In the Western States, milk cous were fed a larger percentage of barley than in any other region and this group was also the highest in miscellaneous concentrates, partly as the result of feeding coura meal in the coastal States,

The percentage of home-group feeds in the dairy concentrate ration averaged 54 percent this fall. A year ago, with farm-grown grains loss plantiful, only percent of the fall ration was home groun. By regions, dairymen reported this ovember the following percentage of their concentrate ration as home-grown: North Atlantic, 23 percent; East North Central, 73 percent; West North Central, 76 percent: South Atlantic, 31 percent: South Central 37 percent: and Western: 26 perent.

POULTRY AND EGG PRODUCTION:

Farm flocks laid 3,498,000,000 eggs in Movember, a record high Hovember production -- . 7 percent

more than in Hovember last year and almost one and one-half times the 1937.46 manage All of this increase was due to a record rate of lay, 9 percent above the previous nigh of last year, which more than offset 2 percent fewer layers. Egg production reached record levels in all marts of the country except the South Central States, However, production in the South Central States was 9 percent above the low production of last year. Total egg production in the United States

CROP REPORT 29 of December 1, 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 10, 1948 December 1, 1948

during the first 11 months of this year was 51,411,000,000 eggs, about the same as a year ago, but 17 percent above average. A 2 percent smaller average number of layers on hand during this period was offset by a 2 percent increase in the rate of lay. Increased production during the 11 months in the East North Central and Western States offset decreases in all other regions.

Egg production per layer in November was 9.5 eggs, the highest of record for the month, compared with 8.7 last year and an average of 6.8 eggs. The rate was at peal levels in all parts of the country. "Increases in the rate above last year ranged from 4 percent in the North Atlantic to 13 percent in the South Atlantic States. Average production per layer on hand for the first 11 menths of this year was 152 eggs, compared with 149 last year and on average of 135 eggs.

The Mation's farm laying flock averaged 365,363,000 layers in Movember -2 percent less than in Movember last year, but 5 percent above average. Humbers of layers were below those of last year in all parts of the country -- decreases ranging from 1 percent in East North Central and Western States to 3 percent in the West Horth Central States. Humber of layers increased about 4 percent from November 1 to December 1, compared with an increase of 6 percent last year and an average increase of 8 percent. On December 1 there were 3 percent fewer layers on farms than a year ago.

Potential layers on farms December 1 (hens and bullets of laying age alus pullets not of laying age) totaled 434,860,000 -- 5 percent less than a year ago and 4 percent below the 1937-46 average. Holdings on December 1 in all parts of the country were below those of a year ago, decreases ranging from 2 percent in the North Atlantic and Western States to 9 percent in the West North Central States. The United States seasonal decrease in potential layers from Movember 1 to December 1 was 8 percent, compared with a decrease of 6 percent last year, which was about average.

There were 59,473,000 pullets not of laying age on farms December 1 - 18 percent less than a year ago and 34 percent below average holdings. Holdings on . December 1 were below those of a year ago in all parts of the country; decreases ranging from 6 percent in the West to 31 percent in the West North Central States. On December 1 about 14 percent of the potential layers were pullets not of laying age to be added to the laying flock this winter, compared with 16 percent a year ago and on exercise of 20 percent.

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 10, 1948 3:00 P.H. (J.S.T.) Maring the second contract of the second cont

Prices received by farmers for eggs in mid-November averaged 58.3 cents per dozen, compared with 53.4 cents a year ago and the 10-year average of 36.9 cents. Shell egg markets were irregular during November with prices tending dominard the latter half of the month. Demand for eggs was good and storage stocks were reduced substantially during the month.

Farmers received an average of 29.3 cents per pound live weight for chickens in mid-November, compared with 29.9 cents in mid-October, and with 24.9 cents in November last year. Demand for chickens was good, with all classes except roasters in ample supply. Compared to last year, Hovember closing prices at Chicago and Eastern Morlots were 9 to 13 cents higher on heavy type foul, 5 to 14 cents higher on light type foul. Eastern Markets ranged from 1 to 3 cents lower on fryers and broilers.

Turkey prices on November 15 everaged 46.1 cents - 26 percent above the previous record high for November in 1946. This compares with 35.7 cents last year and with the 1937-46 average of 25.0 cents. Live turkey markets were very firm and prices advanced charply during November. Stocks of turkeys cleared readily despite the record high prices. Storage stocks of turkeys on November 1, 1948 were 34 million pounds, compared with 65 million pounds a year ago.

The average cost of the United States farm boultry ration in mid-November was \$3.59 per 100 pounds, compared with \$3.68 in mid-October, and with \$4.71 in: November a year ago. Mainly because of lower feed prices, the agg-feed ratio is the most favorable since 1943, the chicken-feed ratio the most favorable since 1944, and the turbey feed ratio the most favorable since 1931.

1/ Season begins with the bloom	of the year	show	n and en	is with	the complet	ion of harvest the

Tollowing year. In California picking usually extends from about Oct. 1 to Dec. 31 of the following year. In other States the season begins about Oct. 1 and ends in early summer, except for Florida limes, harvest of which usually starts about April 1. Estimates of production include fruit consumed on farms, sold locally, and used for manufacturing purposes, as well as that shipped. Fruit ripened on the trees but destroyed by freezing or storms prior to picking is not included. Fer some States in certain years, production also includes some quantities denated to charity, unharvested, and/or not utilized on account of economic conditions. In 1946 and 1947, estimates of such quantities were as follows (1,000 boxes): 1946, Calif. Navel & Misc. orangec - 485; Valencias, 454; grapefruit, Dosert Valleys- 13; Fla. Early & Midseason oranges -900; tangerines -800; grapefruit, seedless -800; other, 1,800; Texas grapefruit -500; Ariza grapefruit, 923; 1947 Calif.Navel & Miscellaneous oranges -521; Valencias, 436; grapefruit, Desert Valleys - 16; Fla. tangerines -600; grapefruit, seedless -2,400; other, 1,300; Texas grapefruit - 2,300. Ariza Navel and Miscellaneous oranges -6; grapefruit -344. 2/ The indicated production for 1948 is based on reported prospects on December 1. 3/Includes small quantities of tangerines. 4/Net content of box varies. In Calif. and Arizana the approximate average for oranges is 77 lb. and grapefruit 65 lb. in the Desert Valleys; 68 lb. for California grapefruit in other areas; in Florida and other States, oranges, including tangerines, 90 lb. and grapefruit 80 lb.; California lemons, 79 lb.; Florida limes, 80 lb. 5/In California and Arizona, Navels & miscellaneous.

ACREAGE AND PRODUCTION OF CROPS, 1948

The total output of crops in 1948 far exceeds that of any other year. The growing season was so favorable that, with the improved farm practices of recent years, new record yields per acre were set for several crops. The composite yield of all crops surpasses any previously known, Acreage abandonment was rather light, so that total harvested acroage is relatively large. Quality of cross, as well as quantity, is also outstanding.

All indexes stamp 1948 as a year of outstanding crop production. The aggregate volume of all crops is 137 percent of the 1923-32 base, 11 points above the previous high mark of 126 percent attained in 1946. The total harvested acreage of the 52 principal crops is about 0.6 percent larger than in 1947 and 1.3 percent larger than the 1942-46 wartime average. The composite yield index is 151 percent of the 1923-32 base, compared with the previous high of 136 percent in 1942. Thus, both high yields and a relatively large acronge are factors in the huge volume of 1948 crops.

Corn leads the procession of record-breaking crops with an outturn of 3,651 million bushels of excellent quality. Not only does this exceed the previous record of 1946 by about 400 million bushels, but the yield of 42.7 bushels per harvested here is 6 bushels more than ever before obtained. Final returns place Plansock in the class of record crops, along with soybeans, pecanuts, rice, pecans and cranterries. Wheat production was exceeded only in 1947. Others in this near-record group are onts, sorghum grain, potatoes, dry beans, popcorn and citrus fruits. Larger than average crops of hay, cotton, barley, tobacco, sugarcane for sugar, hops, grapes, cherries and apricots were harvested. But me, buckuheat, dry peas, coupeas, velvet beans, succepotatocs, sorgo and sugareane sirup, sugar beets, mable products, broomeorn, apples, peaches, pears, plums and prunes are below average in production.

The growing season became favorable to ideal after a poor start in some areas. Heavy rains and waterlogged fields in the fall of 1947 reduced sown coreages of grain in the South. In contrast, Great Plains fields were so dry in the early fall that proporation and seeding operations were seriously delayed. Nevertheless, rains fell in mid-November and a record acreage was sown to winter wheat, as growers continued seeding well beyond usual dates. Fall seeding conditions were excellent in other areas. Favored by mild weather in the early part of winter and by snow-cover when weather became severe, the late plantings prospered. . Harly spring brought wet fields again in the South, frost that killed oats in the Southwest, damaging frought in California, and dry weather in the Great Plains that threatened the poorly-de-cloped wheat. But in late April, weather became more favorable, spring work progressed rapidly, and much of the backwardness of the season was overcome. In Marsome deterioration of wheat occurred in the Great Plains. Timely spring rains followed, which enabled winter wheat to develop miraculously and produce unempectedly high yields. The bulk of spring grains were seeded on time under satisfactor; conditions and corn planting was largely completed by June 1, earlier than the usual.

During July, conditions were in such fine balance that maximum progress resulted for corn and cotton in the same area, and for small grains, sorbeans and corn. Some exceptions to this ideal situation were heavy rains that delayed harvest in Kansas, with local harvesting losses, a best wave in the upper Missouri-Mississippi Valley that forced some grains to maturity, and extreme temperatures in August that may have limited the entent to which corn yields might have gone. The fall continued favorable for development of late growing crops and for fall seeding, Although in a large southeastern area heavy roins and floods interfered with cotton picking and completion of

CROP REPORT December 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 3:00 P.M. (E.S.T.)

harvest of late crops, with some losses. Farmers were able to keep abreast of their work during the 1948 season by increased use of power equipment, so that delays caused by weather were readily overcome. Fertilizers were used in increased quantity. Transportation and handling facilities were again temporarily inadequate, but only negligible losses occurred from piling grain on the ground. As winter closed in, farm work was well advanced, especially fall plowing.

Nearly 351 million acres of the 52 principal crops were harvested in 1948: this is almost 2 million acres more than in 1947. Except for the $352\frac{1}{2}$ million acres in 1944 and the range of $351\frac{1}{2}$ to 362 million acres in the 1928-32 period, the current total exceeds that in any other year in the series which begins in 1909. Changes in total acreages viewed by geographic regions, reflected the kind of crop season. In the North Atlantic region, the total is only slightly larger than the record low acreage in 1947. In the important North Central region, in which annually more than half of the country's crop acreage is harvested, the increase over 1947 was about 2.5 million acres. The $195\frac{1}{2}$ million acres this year in that region have been exceeded only in 1930 and 1932, in the 20 years of record. In the South Atlantic region, the total harvested acreage declined to the lowest point of record, and in the South Central area the total dropped a million acres below the already low level of 1947. Western States expanded their harvested acreage of all crops to a new high point of 394 million acres. In 3 States -Ohio, Indiana, Illinois, Michigan, Montana, Arizona, Nevada, Oregon and California --1948 harvested acres were the largest in 20 years of record and in numerous other States they were near the top.

The net planted acreage of principal crops amounts to 362.2 million acres. about 3.7 million more than in the preceding season. This total was exceeded in 1944, in 1937, and each year of the 1929-33 period. The largest aggregate planted acreage was 3752 million acres in 1932. Planting of such a large acreage in 1948 reflects not only the persistent efforts of growers to sow winter wheat despite adverse conditions in the fall of 1947, but also the favorable spring season. Another factor is that most of that acreage on which winter wheat was abandoned was replanted to sorghums, corn, or spring grains, depending on the area. Since livestock numbers are at a relatively low level, less hay was reouired, and probably a half million acres of hay meadows were plowed up and planted to annual crops. Low carryover stocks of feed grains led to increases in cats, barley, corn and sorghums. Participation in production programs curtailed acreages in potatoes and tobacco, while support prices comparative income per acre of crops and other economic factors, as well as increased mechanization of farms and uncertainty about the labor supply early in the season were factors contributing both to shifts between crops and to more extensive farming methods.

Acreage loss, the difference between planted and harvested acreages of crops, amounts to nearly 11.4 million acres. While larger than the 9.6 to 10.4 million acres lost in each of the preceding 3 years, this total is less than in any year between 1931 and 1944. Major losses resulted from winter kill and spring drought damage to late-planted and poorly developed winter wheat. For most other important crops, acreage losses were relatively light. In most instances effects of adverse factors were reflected in decreased yields or harvesting loss in local areas. Losses due to hail, local floods, tropical storms, frosts and the like, appear to have been lighter than in most years. The quality of most harvested crops was good to excellent.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:00 P.M. (E.S.T.)

Yields per acre in 1948 are above average for most crops. Several reached new heights, including corn, cotton, oats, soybeans, potatoes, tobacco, and dry beans. The yield of flaxseed has been exceeded only once, in 1905, and one would have to go back more than 40 years to find higher yields of barley, and 30 years for popcorn. Because of the large acreage, rice and peanuts both reached record production, although yields were slightly below average. Dry peas and sugarcane for sugar also yielded below average. These individual yields when combined into a composite yield of all crops, result in an index of 151 percent of the 1923-32 average. The nearest approaches to this were 136 percent in 1942 and 134 percent in 1946.

An unprecedented total of nearly 179 million tons of grains was harvested in 1948. This is nearly 40 million tons more than in 1947 and 17.6 million tons more than the previous peak in 1946. Of this, the 4 food grains account for 41.4 million tons, which is 5 percent less than in 1947. Included are the second-largest wheat crop, a record rice crop, but small crops of rye and buckwheat. Feed grains total 137.4 million tons, which is 44 percent more than the small total last year and 11 percent above the 1946 record.

This year's total includes a record corn crop, the third largest oats crop, the second largest crop of sorghum grain and an above average barley crop. Carryover stocks of all fead grains were relatively small; nevertheless, the supply per animal unit will be the largest in history, as grain-consuming livestock during the 1948-49 season will number less than in most recent years. Supplies of hay and roughage also are ample for current livestock numbers, as the few deficit areas have taken steps to adjust livestock numbers to the supply or have purchased hay. Even with grazing available later than usual in many areas, heavy feeding of concentrates is reported this fall.

Oilseed crops produced in 1948 total nearly 151 million tons, exceeding production in any other year of record. This total is 23 percent more than in 1947 and 44 percent above average. It is swelled by record tennages of soybeans, flaxseed and peanuts, and a cottonseed tonnage likely to be nearly onefourth above average. A favorable summer season brought about a record yield mor acre of cotton, despite some damage and loss in November; the current crop is one of the larger cotton crops.

Tobacco production of 1.898 million pounds is well below that in recent years because of reduced acreage, although the highest yield of record was obtained. A big burley crop was harvested, but most other types fell below the 1947 outturn. Production of sorgo sirup is the least of record and sugarcane sirup far below average. Sugar production from be to and cane is likely to total about 1,850,000 tons, one-sixth less than in 1947, with bests below average and sugarcane above average production. Though the acreage of potatoes was reduced to about three-fourths of average, a record yield of 212.4 bushels per acre brought the outturn up to the third largest in history. The sweetpotato crop is one of the smallest in the century.

Seed crop production for 1948 shows sharp changes from last year. The timothy and redtop seed crops are much smaller than in 1947 and reflect the downward trend in acreage harvested. This year's crop of alfalfa seed is the smallest since 1942. The sweetclover seed crop, although only 7 percent smaller than last year, is 38 percent below average. These sharp declines, however, are more than offset by large seed crops of alsine clover,

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17,31948 D.conber 1948 3:00 P.M.(E.S.T.)

Sudar-grass, lespedeza-leading so d crop for the South, and red clover -- leading rotation legume crop for the Corn Belt. he 1948 production of these eight kinds of seeds totals 510.9 million pounds, 4 percent larger than last year, but 6 percent smaller than average;

Deciduous fruit production in 1948 totaled 12 percent less than the heavy outturn in 1947 and 5 percent less than average. Each important deciduous fruit was below last year, except sour cherries and apricots; and each was below average, except grapes, sour cherries, and apricots. Citrus production for the 1942-49 season is forecast about the same as in 1947-48. A small increase in oranges about offsets a decrease in grapefruit. Pecans are a record crop, and walnuts, almonds, and filberts each are large crops.

The combined tonnage of the 25 commercial truck crops produced for fresh market in 1948 was larger than in any other year, except 1945 and 1946. Sweet corn was the only one setting a new production record, but in only one other year were outturns of cauliflower, celery, eggplant, escarole, letiuce, and peppers exceeded. Per acre yields were generally above last year and average, with yields of cauliflower, celery, and cucumbers the best of record. Acrese was 2 percent lower, but the composite yield of fresh market crops was about 7 percent hi her than last year. Commercial truck crops for processing total 5.5 million tons, 2 percent less than in 1947, but 13 percent more than average. These crops were harvested from 1.7 million acres in 1948. Record large production of sweet corn and green lima beans were obtained. Tields per acre of sweet corn and tomatoes are the best of record, while only those for asparagus, green peas, and spinach are below average.

CORM: A record corn crop was produced in 1948. This year's production of 3,651 million bushels is about 1 and one-half times as large as the relatively small crop of 1947 and exceeds the previous record established in 1946 by about 12 percent. Froduction exceeded 3 billion bushels during the war years of 1942 and 1944 and again in 1946, but this is the first year it has reached the 3 and onehalf billion bushol mark. Estimates of all corn production include, in addition to corn for grain, the grain equivalent production of corn for silage, forage, hogging and grazing.

The United States yield per acre, 42.7 bushels, is about 11 bushels above average and exceeds the previous record established in 1946 by 6 bushels. Hybrid varieties were planted on 75 percent of the total acreage, this year, but on most of the high-yielding Corn Belt acreage. This contributed to the recordhigh yield per acre. The harvested acres to was only about 2 percent above the relatively small 1947 acreage but about 5 percent below average. A larger than usual proportion of this year's crop was harvested for grain. Of the 1948 harvested acreage, 91 percent was harvested for grain (which reflects this year's good quality), 5 percent for silage, and 4 percent for forage or hogging and grazing. Last year, 89 percent of the harvested acreege was for grain, 6 percent for silege, and 5 percent for other uses. Less than 1 percent of the 1948 planted acreage was abandoned -- the smallest since 1928.

In contrast to 1947, weather conditions were generally favorable this season. Although wet weather delayed plantings and necessitated considerable replanting in parts of the country, particularly in some southern and northeastern States, plantings were made during the optimum period in the important producing States. Moisture was adequate in most areas throughout the growing season with sufficient

CROP REPORT

BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORTING BOARD

Washington, D. C., December 17, 1948 3:00 P.M. (E.S.T.)

subsoil moisture being available when needed. Dry weather during late summer and early fall hastened the maturity of the late corn crop and aided silo filling, which was completed with little interruption in the principal dairy areas. Practically all corn reached the "safe from frost" stage before the widespread freeze that occurred about mid-October. Light frosts occurred during early October in the northernmost parts of principal corn States and were beneficial in areas where it was desirable that further vegetative growth be stopped. The 1948 crop was also one of the best from the standpoint of quality.

In the Corn Belt, weather conditions were very favorable during most of the season and record or near-record yields were realized in all States. Corn matured somewhat earlier than usual. Rains during late October and in November interrupted corn picking somewhat, but facilitated the use of mechanical pickers where stalks and shucks had become too dry and trittle. Above normal temperatures accompanied by high laumidity during November caused slight molding, particularly in sections of Illinois and Indiana. Most of the corn was of excellent quality and suitable for storage.

In the South Atlantic States, plantings were delayed by heavy spring rains. However, most of the early obstacles were overcome by July and conditions were favorable the remainder of the season, with higher than usual yields in all States except Florida.

Weather in the South-Central States was ideal for harvesting operations. Although yields were above average in all States, the yields in Arkansas and Oklahoma were not as high as indicated in November. Dry weather during late summer had an adverse effect in local sections.

Above-average yields are reported from most of the Mastern States. Yields from irrigated land were very high, but nontralgated yields were somewhat lower than expected earlier in the season.

WHEAT: Wheat production totaled 1,288 million bushels in 1948, less than the 1947 record crop of 1,367 million bushels but 37 percent larger than the 10-year average. This is the fifth consecutive year that production of all wheat has exceeded a billion bushels. Although dry weather greatly delayed plantings of winter wheat in a large part of the central and southern Great Plains, rains came in time and by seeding beyond the usual dates, farmers were able to plant slightly larger acreage than in the fall of 1946. However, winterkill and peor germination, largely due to insufficient moisture last fall, caused fairly heavy abandonment in most of the States in the Nation's bread basket. As a result, the acreage of winter wheat harvested was 4 percent less than last year. Wet weather during the spring wheat planting season prevented the planting of as much acreage as intended and the acreage of all wheat harvested this year fell about 3 percent below the record acreage harvested in 1947.

Weather during the growing season was generally favorable, but excessive rains in June and July cut yields in several States from Indiana to the Atlantic Coast. The important wheat States of Kansas, Oklahoma, Texas, South Dakota, Idaho, and Colorado had lower yields then last year. The result was a national average yield of all wheat a half bushel lower than in 1947.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C. December 17, 1948 December 1948 3:00 P.M. (E.S.T.)

The 1948 winter wheat crop of 990 million bushels is the second largest of record, surpassed only by the 1947 crop of 1,068 million bushels. A record high of 58,161,000 acres was planted in the fall of 1947 and the acreage might have been larger had weather and soil conditions permitted farmers to seed the intended acreage. Abandonment of 9.1 percent of the planted acreage resulted in 52,859,000 acres being harvested, almost 2,000,000 acres less than the 54,835,000 acres harvested in 1947. The yield this year, 18.7 bushels per harvested acre, is down from the 19.5 bushel yield in 1947, but is 2.1 bushels more than the average yield of 16.6 bushels. This is the fourth consecutive year that winter wheat production has exceeded 800 million bushels.

A greatly expanded acreage of winter wheat was seeded in the fall of 1947. Much of the increase resulted from a substantial increase in acreage in the North Central States, late seeding after improvement in the soil moisture condition in much of the Great Plains, and expansion of acreage in Inter-Hountain and Pacific Coast States. Dry weather in the Great Plains area, and rain in Southeastern States during the usual planting period delayed operations and reduced the actual planted acroage below that intended. Germination and plant development in these areas were comparatively moor up to the dormant meriod. Only limited feed was obtained from wheat pastures in all Great Plains States, except in the Nebraska Panhandle. Loss of acreage from winterkilling was not severe, except in areas where moisture was insufficient to carry the plants through the winter, and in South Dakota where an ice sheet covered much of the wheat area.

Optimum growing conditions prevailed throughout the spring and early summer months in most of the wheat area. In the Great Plains, however, the crop passed through a precariously dry period in April and early May and considerable deterioration occurred. The crop headed very short. But rains in late May and early June revived the crop and the heads filled plume and heavy. Yields of grain in Texas, Kansas, Colorado and Nebraska, the major producing States, exceeded earlier expectations, offsetting the lower yields in the Eastern and Pacific States. Local facilities in the Mid-West were inadequate to handle the large crop and considerable grain was piled on the ground, but this was moved under cover later with negligible loss.

The five States of Webraska, Kansas, Colorado, Oklahoma and Texes produced 519,546,000 bushels this year, or 52 percent of the U.S. total production.

SPRING VALAT: Spring wheat production is estimated at 298, 308,000 bushels, only slightly less than the 299,138,000 bushels harvested in 1947, but 17 percent above the 1937-46 average of 254,017,000 bushels. Acreage of all spring wheat harvested this year was 19,045,000 acres, a reduction of 3 percent from the 19,554,000 acres harvested in 1947, but 11 percent above the 10-year average of 17,107,000 acres. Yield per acre is estimated at 15.7 bushels, compared with 15.3 last year and the 10-year average of 14.9 bushels. Wet weather last stringprevented the planting of as large an acreage of hard spring wheat as had been intended and part of this acreage was shifted to durum wheat. Yields also were reduced from earlier expectations by wet weather at harvest in the Pacific Northwest. Abandonment was slightly more than last year, although well below average.

DURUM NEEAT: Durum wheat production is estimated at 44,742,000 bushels, virtually the same as in 1947, compared with the average of 34,619,000 bushels. The acreage harvested this year was 3,187,000 acres, and increase of 8 percent over the 2,948,000 acres harvested in 1947, and 25 percent above average. Yield at 14.0 bushels per acres was the same as the average, but was a bushel less than last vear.

CROP REPORT as of December 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOFRD

Washington, D. C., Lecember 17, Dacember 1948 3:00 P.M. (E.S.T.

Production of Other Spring Wheat, estimated at 253,566,000 bushels, is only slightly less than last year, but is 16 percent above the average of 219,398,000 bushels. Acreage of other spring wheat harvested this year was: 15,858,000 acres. a reduction of 5 percent from the 16,606,000 acres harvested in 1947; but 9 percent more than the 1937-46 average of 14,558,000 acres. The average yield per acre this year was 16.0 bushels compared with 15.3 bushels last year and the 10-year average of 15.1 bushels. In the Dahotas, part of the acreage intended for other spring wheat was seeded to durum, as unfavorable weather delayed seeding beyond the optimum time for hard spring wheat. In the Northwestern States from Montana to the Coast, part of the acreage that could not be seeded to spring wheat was shifted to other crops such as corn, flax and barley. Seedings were reduced in North Idaho, but seedings were increased in both the irrigated and non-irrigated areas of south Idaho.

OATS: The 1948 cat crop is the third largest in history. This year's crop, estimated at 1,491,752,000 bushels, has been exceeded only by the record crop of 1.536 million bushels in 1945 and the 1946 crop of 1.498 million bushels. The 1948 crop is 292 million bushels or nearly a fourth larger than the 1947 crop. and 260 million or more than a fifth larger than the 1937-46 overage. The four leading States -- Iowa, Minnesota, Illinois and Wisconsin -- produced 52 percent of this year's crop, a proportion higher than usual.

Farmers of the Nation planted 44,529,000 acres to oats for harvest in 1948, which is 5 percent more than in 1947 and 6 percent more than average. Of the planted acreage, 9.7 percent was abandoned or diverted to uses other than for grain in 1948 compared with 9.1 percent in 1947. The acreage planted for harvest in 1948 was materially increased in some North Atlantic and nearly all North Central States. In a few States, mostly in the South Central area, unfavorable c conditions at planting time prevented growers from planting the full acreage planned. The loss of acreage during the growing season and at harvest was less than in 1947 in nearly all areas, especially in New York, Pennsylvania, Ohio and Indiana. In Kansas and Oklahoma, unusual acreage losses occurred because of excessive rainfall at harvest while an unseasonable hard freeze in March killed a large acreage in Texas. The freeze was also very damaging in Oklahoma.

The average yield per acre harvested of 37.1 bushels for 1948 is the highest on record and compared with 31.2 in 1947 and 32.3, the 10-year average. The previous record was 37.0 bushels established in 1915. By States, the 1948 yield was equal to or above 1917 in all but 11 States. In only 7 States was the yield below the 10-year average and these States were mostly in the South Central area which experienced excessive moisture in the late growing season and at harvest. time. Yields were generally higher than a year ago in the North Central States, especially in Ohio, Indiana, Illinois and Iowa.

BARLEY: Barley production in the United States is larger this year than last due to both an increased acreage and a higher yield. Production for 1948 is estimated at 317,037,000 bushels, up 13 percent from last year and 6 percent from the 1937-46 average. Except for the years 1941, 1942 and 1943 this is the largest production since 1928. In both the North Central and Western groups of States production was 14 percent above last year. In Minnesota, North Dakota, South Dakota, and California, where 55 percent of this year's crop was produced, the increases over last year are 32, 8, 11 and 14 percent, respectively.

OROP REPORT as of December 1948.

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17. 1948 December 1948 3:00 P.M. (E.S.T.)

The yield for the country as a whole this year was 26.3 bushels per acre, 0.8 bushel more than last year's relatively high yield, and 2.6 bushels more than average. In addition to the favorable season for barley, the use of disease resistant varieties contributed to the high yield per acre this year.

Because of the short 1947 corn crop, the strong demand for feed resulted in the seeding 13,295,000 acres to barley -- 10 percent more than the acreage seeded last year. Also, wet weather at oats seeding time caused some barley to be substituted for acreage not seeded to oats: Of the acreage seeded for harvest this year. 12,046,000 were harvested for grain; this allows for 9.4 percent abandoned and diverted to other uses. Last year 9.0 percent of the seeded acreage was not harvested for grain, while during the years 1937-46 about 14 percent was abandoned and diverted.

The 1948 rye crop is estimated at 26,388,000 bushels, 2 percent more than the 1947 crop of 25,975,000 bushels, but 29 percent less than the 1937-46 everage of 37,398,000 bushels. The acreage of rye harvested for grain this year, estimated at 2,097,000 acres, was 4 percent above the 2,010,000 acres last year, but was 31 percent below the average of 3,055,000 acres. Abandonment and diversion of planted acres to uses other than grain (such as pasture and winter cover) was about 45 percent this year, compared with 46 percent in 1947.

Although the seeding of the 1948 rye crop was somewhat delayed by dry soil in the main producing areas, and harvesting and threshing operations were delayed by rainy weather in the Eastern Seaboard States, the season was generally favorable for the crop. The yield of 12.6 bushels per acre compares with 12.9 last year and the 1937-46 average of 12.1 bushels per acre.

South Dakota again ranks first in both acreage and production this year with North Dakota second, Minnesota third, and Nebraska fourth. Yields per acre were lower than last year in the Dakotas and Minnesota, while in all other North Central States yields equalled or exceeded those of last year. Production in the North Central States was 20,964,000 bushels, about four-fifths of the Nation's total, compared with 19,830,000 bushels last year.

BUCKWHEAT: A relatively small production of buckwheat -- about 6,324,000 bushels -was harvested in 1948. Buckwheat crops in recent years have been only about half as large as those in the first quarter of the century, but except for those of 1939 and 1941, the 1948 crop is the smallest of record. The current crop is a million bushels less than 1947 production.

Reduced acreage in buckwheat is the major reason for the small production. of 355,000 acres sown, 337,000 acres were harvested, both of which are less than two-thirds that in 1947, and well below average. Buckwheat is important as an emergency "catch-crop" in many sections, sown when efforts to plant other crops in proper season have not succeeded. Because of the favorable planting season in the spring of 1948, use of buckwheat as a catch crop was largely unnecessary, so the acreage was more nearly limited to the usual sections. The season was favorable for the development and harvesting of buckwheat, with the result that the yield of 18.8 bushels per acre has seldom been exceeded. New York and Pennsylvania produced nearly two-thirds of the country's total, with Wisconsin, Ohio, Hichigan and Minnesota each accounting for about 4 to 7 percent of the total.

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17. 1948 December 1948 3:00 F.M. (E.S.T.)

The Nation's 1948 flaxseed crop is estimated at a record 52,533,000 bushels, nearly a third more than was produced in 1947 and almost twice the 10-year average production. This year's large crop was harvested from a nearrecord acreege of 4,737,000 acres that yielded 11.1 bushels per acre, the highest yield since 1905, when the mish was 11.8 bushels. The 1948 crop exceeds by 2 and one-half million bushels the previous record of 50,009,000 bushels produced in 1943 and is far above the next ranking crops of 40,976,000 bushels in 1942 and 40,536,000 bushels in 1947. Minnesota retained its position as the leading State in 1948with a production of 19,102,000 bushels, followed by North Dakota with 14,896,000 bushels, and South Dakota with 7.788,000 bushels. These three North Central States produced four-fifths of the Nation's crop of flarseed even though a very sharpincrease occurred in Texas and some western States, particularly Arizona and California.

The near-record 1948 yield of 11.1 bushels per acre harvested compares with 10. bushels in 1947 and the 10-year average yield of 9.0 bushels. The growing season was unusually favorable in nearly all sections of the country, especially in the North Central States where even very late seedings reached maturity and produced good yields. Yields were seriously affected by unfavorable weather in Kansas, Texas, and Oklahoma, but the acreage grown in these States is relatively small.

Only 3.1 percent of the acreage planted for harvest this year was abandonedthe same as in 1947. The average acreage loss is 9.7 percent. Acreage losses this year were only a third of average with the largest loss reported in Kansas as a result of generally unfavorable growing and harvesting conditions. Farmers planted 4,889,000 acres to flax for send compared with 4,161,000 acres last year.

FLAX FIBER: Oregon flax fiber production, placed at 3,400 tons of straw, is down sharply from the 1947 crop of 9,200 tons. The 2,000 acres harvested for fiber in Oregon this year is 2,900 acres, or 50 percent less than the acreage harvested last

The 1948 production of flaxseed from Oregon fiber flax acreage is estimated at 19,400 bushels, compared with 59,000 bushels last season.

Once again the current year's rice crop exceeds that of any previous year. The crop of 81 million bushels produced in 1948 is nearly 4 percent larger than the revised estimate of $78\frac{1}{2}$ million bushels for 1947, and nearly doubles annual production in the 1926-35 decade. This outturn is due largely to the record acreage, as the yield per acre is slightly below average. Abandonment of seeded acreage was negligible in 1948, running heaviest in Louisiana.

About 1,757,000 acres were sown to rice in 1948, of which 1,743,000 acres were harvested, each about 3 percent more than the previous high acreage set in 1947. The yield per harvested acre was 46.6 bushels, slightly about the 46.2 bushels in 1947, but less than the average of 46.9 bushels. Each Isouthern rice-growing State produced more rice than in 1947, which more than offset the decline in California due to a shortage of irrigation water.

Arkansas rice growers enjoyed an unusually favorable season from planting to harvest, obtaining a relatively high yield of 52.5 bushels per acre on a record acreage. But in Louisiana, after a favorable planting season, a summer irought brought lowered prospects and salt water intrusions in some areas; Although heavy rains fell in September, much damage had been done to yields and quality, with some loss of acreage. The yield is considerably below average

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 17 December 1948 3:00 P.H. (E.S.T.)

on the relatively large acreage harvested. Texas rice grovers had barely enough water for their expanded acreage, the largest in their history, and the yield fell below average. We measurable storm damage occurred in any southern rice section.

In California the acreage in rice was limited by short irrigation vater supplies at the time of seeding, but a relatively large acroage finally was sown. The cool sensen retarded development of the crop and harvest was unusually late. Dry weather in Movember, however, permitted harvest to continue without interruption or field loss, though some immature fields remained unharvested on Docember 1. Yields and quality are relatively low for this State.

ALL SORGHUIS (INCLUDING SIRUP): The 1948 sorghum grain crop of 131,644,000 bushels is the second largest of record, exceeded only by the 185 million bushel crop of 1944. The 1948 crop was 37 percent larger than the 1947 crop of 96,016,000 bushels and was nearly one-third greater than the 10-year average of 100 million bushels. The average yield per acre of 13.0 bushels was nearly a bushel above that of 1947. Yield per acre was above 1947 in all States except North Carolina, Texas, Arizona and California. In these States, however, the lower yields were off-set by larger acreages harvested for grain. Production this year was greater than in 1947 in every State.

Sorghum forage production of 7,616,000 tons was one-fourth greater than in 1947. This gain resulted from both a larger acreage and higher yields per acre. The average yield of 1.48 tons was well above the 1.25 tons of 1947 and was equal to or greater than the yield in 1947 in all States except Kentucky.

Sorghum siloge production of 4,549,000 tens was 32 percent greater than the 3,448,000 tons produced in 1947. The yield per acre of 7.19 tons in 1948 compares with 5.15 tons in 1947. The higher yield was a strong factor in reducing the acreage utilized for silage.

The acreage planted to all sorghums for the crop of 1948, at 13,813,000 acres, was 18 percent (reater than the 1947 acroage, but 18 percent less than the 1937-46 average. Acreage of sorghums not harvested for any purpose (lost completely) amounted to 5 percent in 1948 compared with 4 percent in 1947 and the 10-year average of 7 percent. The less than usual proportion of the acreage not harvested in 1948 was due to a favorable season in the more important areas. Grain sorghums developed to maturity with practically no frost injury. Drought effects were largely localized and were confined primarily to central and southwest portions of Oklahoma, resulting in some reduction in yield per acre but little loss of acreage.

Utilization of the 13,185,000 acros of all sorghum harvested in 1949 tended to follow the general pattern of 1947 with the largest proportion being Parvested for grain, followed in order by forage, silago and sirup. The utilization in 1948 was 55.4 percent for grain, 39.0 percent for forage and 4.8 percent for silege. There has been a decided shift in utilization compared with the 10-year average which included several years when there was more emphasis on the production of forage. The 10-year average utilization was 39.6 percent for grain, 53.7 percent for forage and 5.5 percent for silage. Use for sirup is of minor importance, being usually about one percent of the total harvested acreage.

POPCORD: Popcorn growers in the 12 Commercial States for which estimates are available produced nearly 300 million pounds of popcorn this year, compared with 102 million pounds last year. Estimated production this year is the second highest of record and compares with the record crop of over 428 million pounds

- 13 -

CROP REPORT
as of
December 1943

CROP REPORTING BOARD

Washington, D. C., December 17, 1948 3:00 P.M. (L.S.T.)

produced in 1945. Production this year in practically all producing States was above last year except in California with the production in Illinois and Hentucky topping all previous records. Illinois was the leading popcorn State this year, barely nosing out Iowa with each State producing nearly 63 million pounds. Ohio production was over five times that of last year. The 10-year average U. S. production is 171 million pounds.

The planting season this year was generally favorable in most producing areas. The harvest season was also favorable except in scattered localities and quality of the 1948 crop is reported to be good to excellent in most areas. The unusually high production this year for the country as a whole—nearly three times the 1947 output—was due partly to an increase in the acreage harvested, but primarily to the unusually high yield of 1,966 pounds per acre, compared with 1,240 pounds lost year and the 10-year average of 1,437 pounds.

Currently, estimates are prepared for only 12 producing States, but it is known that sizeable quantities of popcorn are produced in Colorado, Idaho, Tonnessee and Virginia. Although no official estimates for these States are available, production in each State runs well into the millions of pounds. Indications are that the crop in Colorado is three times as large as last year.

Growers in the 12 States harvested 149,100 acres, compared with 82,500 peres harvested last year. The harvested acreage in most of the 12 States was larger, than last year, with Oblahoma harvesting almost five times the acreage in 1947. Acreage losses this year were 2.3 percent of the planted acres, compared with 3.7 percent last year. In general, 1948 was an ideal year for popcorn. Yields per acre were good in all of the main producing States with the yield in four States averaging 2,500 pounds or better. The increased use of hybrid seed and more fertilizer has been partly responsible for increased yields in most States this year. In Illinois, hybrids accounted for 78 percent of the error.

TOBACCO: A total production of 1,898 million pounds of tobacco is estimated for 1948. This compares with 2,110 million pounds produced in 1947 and the all-time record high of 2,322 million pounds harvested in 1946. The reduction was brought about by lower acreages. The average yield in 1948 at 1,234 pounds per acre broke the record established in 1946 when 1,182 pounds per acre were produced, and compares with the 10-year average yield of 1,008 pounds. The acreage harvested declined to 1,536,000 acres compared with 1,845,000 acres in 1947 primarily because of lower acreage allotments for 1948 flue-cured tobacco.

The estimated production of <u>flue-cured</u> tobacco is 1,081 million pounds, 236 million pounds below production of 1947. The acreage in 1948 is placed at 503,000 acres, only 76 percent of that of last year and 92 percent of the 10-year average flue-cured acreage.

The <u>burley</u> crop is estimated at 535 million pounds and compares with 484 million in 1947. Average yield is indicated at a record 1,282 pounds per here, compared with 1,171 pounds in 1947 and the previous record of 1,256 pounds in 1946. Growing conditions were generally favorable throughout the season except for some areas in Hentucky where burley was retarded by early drought. All burley States except Ohio and Henses either equaled their record high yield per here or encoded it in 1948. The total burley acreage was little changed from last year. Marketing of burley began the last week of November with heavy sales and is now in full swing.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., Dec'ember 17, 1948 December 1933

A total of 35.2 million pounds is indicated for Southern Maryland tobacco, about 3 million pounds below production of 1947. The reduction resulted from a slightly known horvested acronge and a lower average yield per acre. Some acronge counderment took place due to heavy rains early in the season and to local summer hailstorms.

A crop of 69.8 million pounds of fire-cured tobacco in 1948 compares with 35.8 million bounds broduced last year and 108.9 million in 1946. A poor start in typ's 22 and 23 was largely overcome in mid-season and relatively good yields were realized. Growing conditions were favorable all season in the type 21 area where the average yield per acre equals the all-time high established in 1946.

The dark air-cured crop is placed at 34.9 million pounds, down 6 percent from that of 1947. At 30,100 acres, the total acreage in dark air-cured tobacco is down 15 percent from last year and the lowest of record. The average yield per acre on the other hand was considerably above 1947 and was exceeded only in 1946.

Production of eiger tobaccos is estimated at 141.6 million bounds, or 3 percent below that of 1947. Increases in fillers were more than offset by a substantial decrease in the production of binders. Growing conditions were ideal all season for fillers in both Pennsylvania and Ohio, with only minor damage from hail. A new high record average yield per acre is indicated. Production of fillers at 70.5 million pounds is above that of any recent year. On the other hand estimated production of binders at 57.2 million is below that of any year since 1944.

The crop of wrappers is placed at 13.8 million pounds, practically unchanged from that of last year. The season was generally unfavorable in shade grown area of New England but satisfactory in the Georgia-Florida area.

HOPS: The 1948 crop of hops in the 3 Pacific Coast States totaled 49,819,000 pounds in comparison with 50,098,000 pounds last year and the 10-year average of 43,532,000 pounds. Compared with last year, the Washington crop is up 12 percent, the Oregon crop down 2 percent, and the California crop down 16 percent. The California crop of. 11,362,000 pounds is the smallest since 1942. Hildew reduced yields, especially in the Constal yards. The Washington crop of 22,704,000 pounds is record-large. In Orczon, early growing conditions favored mildew infection; but timely surface winds, high temporatures, and a dusting program checked spread of the disease. Yields in Willamette Valley yards exceeded these obtained last season. but yields in southern Oregon were no better than last season. While the State average yield was better, the acreage harvested and production were below last scason.

HEND: Hemp fiber is now produced only in Wisconsin, and Kentucky is the only State which produces home for seed. This year Wisconsin planted about 3,000 acres and harvested about 2,800 acres of hemp for fiber. Hemp fiber harvested this year is estimated at 990 pounds per acre, compared with 950 pounds per acre last year. Five home mills operated in Wisconsin this year. Last year Wisconsin planted 5,200 acres and harvested 4,900 acres for fiber.

Montucly horvested about 400 acres of hemp for seed, compared with 600 acres lest year. Yield of seed per acre was 440 pounds this year, compared with 465 bounds last. Production of both home seed and home fiber is at a rather low level, compared with the high wartime peak.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:00 P.H.(E.S.T.)

COMMERCIAL APPLES: The commercial ample crop is estimated at 90,288,000 bushels-20 percent less than the 1947 crop and 22 percent less than average. Production now estimated is about three-fourths of last year in the Western and North Atlantic Regions, and two-thirds of last year in the hidwest. The South Atlantic Region produced a crop two-fifths greater than last year's short crop. This year's production was below average in all regions. There was very little economic abandoment this season in any commercial apple area.

Weather was favorable at harvest time in nearly all important sections, The season was earlier than last year in the eastern part of the country but later in the West.

The Washington crop of 26,390,000 bushels is about one-fifth smaller than last year and 4 percent below average. The California crop was only 6,240,000 bushels compared with 11.082,000 bushels last year and an average of 7,780,000 bushels. Gravensteins, the most important California variety, were especially short this season. In the Central States, the crop is about two-thirds of average in Hichigan, less than one-half of average in Ohio and about three-fourths of average in Illinois. In many areas in the Eastern States, hot, dry weather prior to maturity caused a heavy drop and cracking of some varieties, especially Staymans. Compared with average, New York is down 22 percent, Pennsylvania down 44 percent, Virginia down 19 percent, and West Virginia down 28 percent.

The six leading varieties in 1948 in order of crop size are Delicious, Wincsap, McIntosh, Jonathan, Rome Beauty and York Imperial. Each of these varieties had more than 5 million bushels, and combined they comprised more than three-fifths of total commercial production. York Imperial is the only important variety which had a larger production than last year, but the York crop was short last year.

The 1948 peach crop is estimated at 65,749,000 bushels--20 percent less than the 1947 crop of 82,270,000 bushels, but only 1 percent less than average.

California clingstone peaches are estimated at 20,835,000 bushels-3 percent below last year, but 24 percent above average. California clingstones are grown primarily for canning. California freestones, at 9,251,000 bushels, are 20 percent less than last year and 13 percent less than average. Approximately half of this year's freestone crop was sold for fresh use, onc-fifth canned, and one-fourth dried. For the 1947 crop, 42 percent was sold for fresh use, 40 percent dried, 14 percent canned, and 4 percent other disposition.

Production in the 10 early southern States totaled 14,240,000 bushels this year, commared with last year's crop of 22,438,000 bushels, and the average of 17,297,000 bushels.

The North Atlantic States produced a total of 4,705,000 bushels-down 10 percent from last year and down 4 percent from average. The total for the North Central States for this year is 7,207,000 bushels-26 percent less than last year, but 6 percent above average.

The total pear crop is estimated at 26,399,000 bushels, 25 percent less PEARS: than last year and 13 percent less than average.

Bartletts in the three Pacific Coast States totaled 15,135,000 bushels, 26 percent less than last year and 9 percent less than average. The Bartlett crops

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Wachington, D. C., December 17, 1948

December 1948 3:00 P.M. (E.S.T.) are down from last year by about a third in Washington, a fourth in California and about a tenth in Oregon. The Pacific Coast fall and winter pear crop is placed at 5,957,000 bushels, 25 percent less than last year, but 2 percent above average. Production of winter pears by States is 1,775,000 bushels for Washington, 2,932,000 bushels for Oregon and 1,250,000 bushels for California. These estimates compared with last year are 17 percent less for Washington, 22 percent less for Oregon, and 39 percent less for California.

For the States other than Pacific Coast States, pear production totaled 5,307,000 bushels, 23 percent less than last year and 32 percent less than average.

GRAPES: The 1948 crop is estimated at 2,998,100 tons, 1 percent below last season, but 11 percent above the 1937-46 average.

Production in California is estimated at 2,813,000 tons, down slightly from the 1947 crop of 2,824,000 tons, but 12 percent above average. Of the California production, output of wine varieties is placed at 601,000 tons, commared with 517,000 tons last year; table varieties, 583,000 tons compared with 620,000 tons; and raisin varieties, 1,629,000 tons compared with 1,687,000 tons last year. Production of raisins for 1948 is estimated at 223,000 tons. This compares with the 1947 production of 303,000 tons and the 10 year average of 256,050 tons. Nearly one-third of the tonnage of raisin varieties and nearly one-half of the tonnage of all California grapes were crushed for wine and brandy this year in comparison with 16 percent and 34 percent respectively last year.

Total production in the Great Lakes States (New York, Pennsylvania, Ohio and Michigan) was smaller than last year and below average. Washington harvested a record-large crop of 24.000 tons, 12 percent larger than last season and nearly double the 10-year average.

The 1948 plum crop is estimated at 70,500 tons-down 10 percent PLUMS AND PRUMES: from last year and 11 percent from average. The California production of 67,000 tons was 11 percent below average and the Michigan crop of 3,500 tons was 18 percent below average.

Commercial dried prune production in California, Oregon, and Washington totaled 171,450 tons -- down 13 percent from last year and 17 percent from average. The California crop did not turn out quite so well as expected. In late summer many prunes dropped before reaching desirable sizes and sugar content. Out of the production of 177,000 tons, 7,000 tons were not harvested because of small sizes and the high cost of harvesting small prunes in relation to selling prices.

Prunes marketed for fresh consumption in Idaho, Washington, and Oregon totaled 48,900 tons-down 14 percent from last year but 3 percent above average. Very few prunes were canned this year, only 17,300 tons in comparison with 26,170 last year. The quantity frozen was 920 tons this year, compared with 1,250 tons last year, and the 10-year average of 6,620 tons. For the second year in succession, the prune crop was very short in western Washington and Oregon, due largely to spring freezes. In the eastern sections of these States, production was slightly larger than last year and about a fourth above average.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:60 3.1. (J.S.T.)

December 1948

CITRUS: Early and midseason oranges for the 1948-49 crop are estimated as of December 1 at 53.3 million boxes -- 1 percent less than last season, but 29 percent more than average. Hew crop Valencia oranges are forecast at 61.6 million boxes -- 9 percent above last season and 28 percent above average. The grapefruit crop is now indicated at 56.2 million boxes, compared with 61.6 million boxes in 1947-48 and 47.5 million boxes average. California lemons are forecast at 13.1 million boxes, compared with 12.9 million boxes last season and 12.8 million boxes average.

In Florida, most of Movember was dry in the citrus areas, but some rain fell the latter part of November and early December. Temperatures have been above normal. Early and midseason oranges are estimated at 34 million boxes -- 3 million more than last season and 14 million more than average. Valencias are forecast at 30 million boxes, compared with 27.4 million boxes last season and 16.5 million boxes average. Grapefruit are placed at 31 million boxes -- 2 million less than last season, but 7 million more than average. Tangerines are estimated at 4 million boxes, the same as in 1947-48 and 19 percent above average. Volume of fruit harvested has been greater this season than last. By November 27, a little over 7.5 million boxes of oranges, 6.5 million boxes of grapefruit and 1.3 million boxes of tangerines had been harvested. This compares with 5.5 million boxes of oranges, 4.1 million boxes of grapefruit and 431,000 boxes of tangerines harvested by the same date last year.

Conditions in the Lower Valley of Texas were very satisfactory through most of November. While rainfall for the month was light and accumulation for the season is considerably below normal, fall rains were timely and fruit sized well with quality good. Temperatures fell below freezing on November 30. Practically no damage was caused by the cold, but strong winds for two days resulted in considerable defoliation of trees. Oranges are forecast at 4.7 million boxes -- 10 percent less than last season, but 45 percent above average. Early and midseason varieties are forecast at 2.9 million boxes. Texas grapefruit are estimated at 19 million boxes -- 18 percent less than last season, but 9 percent above everage. Movement of oranges to December 1 was 37 percent more than last year to the same date and movement of grapefruit was 15 percent more. Rail movement has been lighter than last year, but truck shipments about double. Movement of Texas lemons to date is only about one-third as heavy as last year. Supplies have been plentiful since November 1, but the demand has not been strong. The crop from the late bloom continues to make good progress and later season yields should be good.

Louisiana oranges are forecast at 320,000 boxes, compared with last season's production of 300,000 boxes and the 10 year average of 298,000 boxes.

Arizona citrus has experienced many frosty mornings, but apparently has suffered no damage to December 1. Hoisture supplies continue critically short. Gravefruit are estimated at 3.6 million boxes -- 20 percent above last season and 9 percent above average. Oranges are forecast at 1.2 million boxes -- 51 percent above 1947-48 and 48 percent above average. Mavels and miscellaneous are forecast at 580,000 bones and Valencias at 600,000 boxes. Lemon prospects are poor. Trees are generally in poor condition and the set is light except on a very few groves which escaped frost damage last winter. Quality of the short crop will be good.

California was still exceedingly dry to December 1. A number of frosty nights have apparently caused no damage to citrus. Several days of dry winds have been detrimental to both citrus trees and fruit. Sizes of navel oranges are very small in

CROP REPORT December 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948, 3:00 P.M. (E.S.T.)

all areas. The crop of navel and miscellaneous varieties is now estimated at 15.5 million boxes -- 18 percent less than the 1947-48 crop and 18 percent less than average The Valencia crop is forecast at 29.2 million boxes -- 9 percent above last season, but 3 percent below average. Sizes are very small again this season. California Desert Valleys grape fruit are estimated at 1.15 million boxes -- 20 percent above last season, but slightly less than average. Harvest of this crop has started. Summer grapefruit are forecast at 1.5 million boxes -- about the same as last season and 7 percent below average.

CRANBERRIES: Production of cranberries in 1948 is estimated at a record of 922,500 barrels -- 17 percent more than the 1947 crop and 37 percent more than average. The Massachusetts crop is estimated at 575,000 barrels, 19 percent above last year and 29 percent above average. Quality this season has been good. Production in New Jersey turned out to be 67,000 barrels -- 18 percent below last year and 22 percent below average. The New Jersey berries sustained heavy loss from sun scald prior to ripening. The Wisconsin crop, at 225,000 barrels, is 40 percent above the previous record in 1947 and more than twice the 1937-46 average. The heavy production is a result of increased acreage combined with unusually favorable growing conditions. <u>Washington</u> harvested 42,500 barrels this year and 48,000 barrels last year, compared with an average of 26,710 barrels. The <u>Oregon</u> crop was 13,000 barrels this year, 14,200 barrels last year and 9,730 barrels average.

CHERRIES: The 1948 cherry crop in the 12 commercial cherry States is estimated at 216,980 tons -- 25 percent more than the 1947 crop and 28 percent more than average.

Sweet cherries, grown principally in the West, are estimated at 80,900 tons -- 2 percent above last year but 7 percent below average. Crops in Washington. Oregon, and California, which make up about four-fifths of the United States total, were each below average, and except in Oregon were below last year. The combined total for all other States is above everage and last year.

Sour cherry production is estimated at a record high of 136,080 tons -- 45 percent above last year and 59 percent above average. Hichigan and Wisconsin each had record crops and all other States except Ohio, Washington and Oregon had crops larger than average. New York, Michigan and Wisconsin combined produced 84 percent of this year's crop.

APRICOTS: Production of apricots in California, Washington, and Utah is estimated at 249,500 tons --- 24 percent more than the small 1947 crop and 4 percent above average. California at 219,000 tons is up 30 percent from last year. Washington at 21,800 tons is down 22 percent from last year, and Utah at 8,700 tons is nearly double the 1947 crop. In California and Utah considerable quantities were not harvested. In both States processing demand was weak and in California the proportion of small sizes was larger than usual. The Washington crop was reduced from last year by spring frost damage.

TIGS. PINEAPPLES, AVOCADOS, California dried fig production is estimated at DATES AND OLIVES: 29,500 tons this year (22,500 tons standard grades and 7,000 tons substandard grades) in comparison with 38,000 tons last year (30,600 tons standard grades and 7,400 tons substandard grades). The 22,500 tons of standard grade figs for this year compares with 27,700 tons two years ago and is the smallest tonnage since 1939. California figs

CROP REPORT as of December 1943

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 3:00 P.M. (E.S.T.

for canning are estimated at 8,400 tons this year and 13,100 tons last year: Figs for fresh use totaled 3,400 tons this year and 2,700 tons last year. Texas figs for preserving are estimated at 560 tons this year and 760 tons last year.

Florida pineapple production at 7,000 crates this year compares with 4,000 last year and the 1937-46 average of 11,000.

Avocado production for 1918-49 is estimated at 15,100 tons in comparison with 16,900 tons for the 1947-48 season. The California crop, reduced by winter injury. in southern counties, is only 12,000 tons in comparison with 14,600 tons the previous year. The Florida tonnage was placed at 3,100 tons this year and 2,300 tons last year. Growing conditions were favorable late in 1947 and in the spring of 1948.

California date production is estimated 12,200 tons this year and 10.180 tons last year. The harvest was below earlier indications because of rain damage.

The California olive crop, estimated at 62,000 tons, is about $1\frac{1}{5}$ times the 1947 crop of 40,000 tons and the largest tonnage since the 1940 crop of 69,000 tons. The size of fruits average smaller than usual but it is expected that all of the crop which is not used for canning will be harvested and crushed for oil. The harvest of olives for oil production will extend well into the winter.

PECANS: The 1948 pecan crop is now estimated 153,812,000 pounds -- 30 percent above the 1947 crop of 118,639,000 pounds and 40 percent above average. This is a reduction of 9 million pounds from the November 1 estimate and 16 million pounds from the October 1 estimate. In comparison with October 1, the Georgia estimate at 39,600,000 pounds is down 5 million, the Alabama estimate at 17 million is down 1 million, the Oklahoma estimate at 12 million is down 6 million, and the Texas estimate at 43 million is down 4 million. No important producing States show increases over the October 1 estimate. In the spring, conditions were unusually favorable for a very large crop of pecans in most areas of the pecan belt except Oklahoma, which produced a record-large tonnage in 1947. Excessive rainfall during July was very favorable for scab development, especially in the States east of the Mississippi River, and in many areas several varieties including Success, Moneymakers, Moores, and Schleys, have not filled well. This has lowered the quality in many groves and reduced the quantity of nuts harvested. In Oklahoma and some areas in Texas, some groves have been left unharvested because of the low quality, low yields per tree, and harvest costs too high in relation to prices being received for pecans.

Most of the increase in pecan production this year over last year is in the States east of the Hississippi River where the improved varieties make up the bulk of the production. Production of improved varieties at 72,321,000 pounds is 61 percent above last year and 55 percent above average. In the States west of the Mississippi River, where the seedling pecan production predominates, much larger crops in Texas. Louisiana, and Arkansas more than offset the sharp reduction in Oklahoma. The United States production of seedlings is placed at 81,491,000 pounds -- 10 percent above last year and 30 percent above average.

ALMONDS, FILBERTS AND WALNUTS: The California almond crop is estimated at 29,600 tons -- 1 percent above last year and 44 percent above average. The 1948 crop, however, is about a fifth less than the record-large tonnage of 37,800 tons produced in 1946. Production varies greatly by localities, being especially light in the San Luis Obispo County area.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:00 P.M. (E.S.T.)

Walnut production for California and Oregon combined, totals 69,900 tons-8 percent above last year and 9 percent above average. The California crop is estimated at 61,000 tons this year and 59,000 tons last year, the Oregon crop at 8,900 tons this year and 5,600 tons last.

The filbert crop in the Northwest did not turn out as well as expected and the 6,940 tons now estimated is down 8 percent from the November 1 estimate. This year's crop is 21 percent less than the large 1947 crop of 8,800 tons, but is 40 percent above average. Filbert production has increased sharply in recent years.

A record large crop -- 67,200 tons -- is indicated for 1948. The revised total for 1047 is 53,200 tons. Large plantings of tung trees have occurred in the Gulf Coast States the past several years and the bearing capacity of the Nation's tung orchards has increased sharply. Production totaled 57,400 tons in 1946; 37,080 tons in 1945; 26,680 tons in 1944, and 6,200 tons in 1943. The 1948 crop is distributed by States as follows: Mississippi 29,000 tons, Louisiana 18,500 tons, Florida 17,000 tons, Georgia 1,200 tons, and Alabama 1,500 tons.

POTATOES: Harvested acreage this year was the smallest in nearly seven decades, but the average yield per acre was a record high and production has been exceeded only twice. The 1948 production of 445,850,000 bushels was exceeded by the 458,887,000 bushels harvested in 1943 and the record production of 484,174,000 bushels in 1946. This year's crop is 15 percent larger than the 389,048,000 bushels harvested in 1947 and exceeds the 1937-46 average production by 14 percent. Growers planted 2,127,000 acres to potatoes for 1948, compared with 1947 plantings of 2,136,000 acres and the 1937-46 average of 2,897,000 acres. The 2,099,000 acres harvested is practically the same as the 1947 acrea e, but only about three-fourths the 1937-46 average of 2,826,000 acres. Abandonment of 1.3 percent was the smallest in recent years.

As early as July it appeared that yields would at least approximate the previous record high vield of 186 bushels in 1946. Conditions were generally favorable throughout the remainder of the growing and harvest seasons and a new record yield of 212 bushels per acre was harvested. This yield is 73 bushels above average. Vields in all States except West Virginia, Delaware, Kentucky, South Carolina, Georgia and Louisiana were above average. The favorable growing and harvesting seasons, an increased proportion of potato acreage on commercial potato farms, use of increased quantities of commercial fertilizer, use of more effective spray and dust programs, and the continued shift to irrigated lands are among the factors contributing to the high yield for the United States.

For the 29 late States, production amounted to 344,202,300 bushels, compared with 295,829,000 best ols in 1947 and the 1937-46 average of 304,280,000 bushels. In 1943 and 1946, when the total crop exceeded the 1948 production, production in the late States was 358,568,000 bushels and 365,280,000 bushels, respectively. For the 18 surplus late States, production of 317,749,000 is 2 percent below the 324,663,000 bushels harvested in 1943 and 5 percent below the 333,016,000 bushels harvested in 1946.

The late potato acreage in the East generally exceeds the acreage harvested in 1947. Conditions in this section of the country favored development of the late potato crop and there was no appreciable damage to tubers from freezing.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:00 F.M. (E.S.T.)

Record-high yields were harvested in Maine, New Hampshire, Vermont, Massachusetts, upstate New York, and Pennsylvania. Production of 130,770,000 bushels estimated for the three eastern surplus late States (Maine, New York and Pennsylvania) is 15 million bushels larger than the 1947 crop, but almost 11 million bushels smaller than the 1946 production.

In the central part of the United States, the downward trend in notato acreage continued in 1948 with each of the late States, except Iowa, contributing to the reduction. However, record-high yields were harvested in Michigan, Minnesota, North Dakota, South Dakota, Ohio, and Indiana. For the 5 surplus late State in this section of the country (Michigan, Wisconsin, Hinnesota, North Dakota, and South Dakota), production of 66,760,000 bushels is 8 percent larger than the 1947 drop, but 8 percent below average. In Michigan, an expansion in potato acreage grown under irrigation contributed to the record yield. Some acreage was lost in the Red River Valley of Minnesota and North Dakota. However, damage from blight that hit some fields, particularly in the northern end of the Valley, was much lest than expected in late August. In West Virginia, the crop was planted late and yields were reduced by blight.

In the West, growers generally increased notato acreage following the attractive prices received for the storage crop of 1947. Increased acreage and record yields in Nebraska, Idaho, Colorado, Utah. Washington, Oregon, and California (late crop) combined to produce a near-record crop in this part of the country. For the 10 western surplus late States, production of 120,210,000 bushels is 29 percent larger than the short crop of 93,274,000 bushels harvested in 1947, but 2 percent smaller than the record crop of 122,399,000 bushels harvested in 1946. In Nebraska a small unharvested acreage was damaged by a freeze toward the end of the season. In Idaho favorable weather prevailed from planting through harvest time. Killing frosts were delayed in this State until mid-October permitting an unusual amount of late growth; however, harvest was completed with practically no frost injury. The growing season was almost ideal in Colorado, especially for the early crop in the northern part of the State and the late crop in the San Luis Valley. The sharp reduction in acreage in Nevada was caused by the uncertain water supply at planting time.

For the 8 intermediate States, production of 36,234,000 bushels is 7 percent larger than the 1947 crop and 11 percent above average. In New Jersey the slight reduction in yield, caused by excessive rains during the growing season, was more than offset as many commercial growers utilized their alloted acreages more fully than in 1947. Yields in Delaware and Maryland were also reduced by excessive rair The commercial and farm crops in Kentucky were reduced by dry weather that began in late May and prevented proper sizing of tubers. Record-high yields were harvested in Virginia, Missouri and Arizona.

For the 12 early States, production of 65,414,000 bushels is 10 percent larger than the 1947 crop and 19 percent above average. A large expansion in the California acreage and small increases in the Morth Carolina and Texas acreages almost offset the reduction in acreage harvested in the other southern States. Production of the early crop in California is almost equal the total production of the 11 southern States. Planting of the early crop in the South was late. The commercial early crop in South Carolina and south Georgia was damaged by excessive rains in April and some acreage was lost. The Tennessee crop started clowly and dry weather during the fruiting period caused further reduction in yield.

BUREAU OF AGRICULTURAL ECONOMICS

Washington, D. C., CROP REPORT December 17, 1948 CROP REPORTING BOARD as of December 1948 3:00 P.M. (E.S.T.)

United States production fell below fifty million bushels this year for the first time in nearly a quarter of a century. The estimated crop of 49,806,000 bushels for 1948 is about one-tenth less than the 55,746,000 bushels produced in 1947 and a fourth below the 1937-46 average of 64,866,000 bushels. Not since 1924 has a smaller crop been produced. The 514,000 acres harvested this year made up the smallest acreage since 1887. It was 13 percent less than last year and 29 nercent below average. Only in Missouri, Iowa, and Indiana were acreages as large this year at last, and in all States they were below average. Much of the production is used on farms where grown, and with farm income at higher lavels the sweetpotato "patch" has disappeared from many farms. Acreage harvested this year was only about one-half the record high of the depression year 1932. The national average yield of 97 bushels per acre is 3 bushels above last year and 8 bushels els above average.

_ Acreage in the important South Central States, where a little more than onehalf of the total is grown, was reduced about an eighth from last year to a level nearly one-third below average. Yields were above average in all of these States except Kentucky and Texas. In the important commercial States of Louisiana, the average yield per acre was one of the highest of record. Rains in August and favorable weather thereafter helped overcome the late, slow start caused by dry weather earlier in the season.

The South Atlantic States, with nearly four-tenths of the total acreage, made a reduction similar to the South Central group. Yields were above average in the more important States. However, in Delaware and Maryland wet weather delayed transplanting, and yields were below average. In Florida, yields were below preharvest expectations, and below average.

The New Jersey crop was transplanted under favorabe conditions and produced good yields, despite a period of dry weather about mid-September, which retarded growth temporarily. In the North Certral States, early-season weather was favorable for vegetative growth, but dry weather in late August and early Sentember reduced yields in Indiana, Iowa, and Kansas. Yields in the San Joaquin Valley of California were very good, despite a late season. Good fall weather prevented losses in fields

Sugar Feet production is estimated at 9,418,000 tons, or 25 percent below last year's record production of 12.504.000 tons. Abandonment was rather heavy, averaging over one-eighth of the planted acreage. Yield on the other hand at 13.5 tons per acre was the third highest of record, exceeded only by the yields of 14,2 tons in 1947 and 13,7 tons in 1941. California with an increase of 11 percent in harvested acreage and with its relatively high yield compared with other areas was largely responsible for the high United States yield per acre. The United States acreage harvested was 700,000 acres compared with 881,000 acres last

Acreages in all the Lake States were down from about 20 to 60 percent while the yields were higher than a year ago except in Wisconsin.

All of the West North Central States except North Dakota showed declines in acreage from 1947. However, yields were above the previous year except in Kansas'.

California was the only Western State showing an increase in acresge over the previous year. Much of this increase resulted from a sharp increase in the acreage planted in the fall of 1947 for hervest in 1948. The fall acreage harvested in 1948 was about four times that harvested in 1946. Fall plantings have now become a sizeable portion of the total California sugar beet acreage.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 Jecember 1948 3:00 P.M. (E.S.F.)

The 1948 yields were down from last year in all of the Western States excent Montana, Production in this area was much less than the previous year because of the sharp drop in both acreage and yield.

Preliminary factory reports point to an expected production of 1,301,000 tons of refined beet sugar from the 1948 beet production. This represents a reduction of 24 percent from the previous year.

SUGARCAME FOR SUGAR: Sugarcane from the 1948 crop to be used for sugar making is now estimated at 5,778,000 tons. This is made up of 4,734,000 tons in Louisiana and 1,044,000 tons in Florida. The volume of sugarcane thus used last year totaled 3,922,000 tons in Louisiana and 920,000 tons in Florida. Sugar production from cane ground from this year's crop is now expected to be 371,000 tons in Louisiana and 87,000 tons in Florida, totaling 458,000 tons, 96 degree raw basis. Last year's production totaled 376,000 tons, consisting of 297,000 tons in Louisiana and 79,000 tons in Florida.

Lack of sufficient rainfall until late August severely retarded early season cane growth in Louisiana and the crop never fully recovered. Yield per acre is now expected to average 18.0 tons, compared with 15.2 tons for the hurricane damaged crop of last year and the 10-year average of 19.2 tons. Yield per acre in Florida this year, now estimated at 29 tons, is above last year but below the average.

Cane grinding is well advanced in Louisiana and progressing in volume in Florida.

SUGARCANE SIFUP: Production of sugarcane sirup in 1948 is estimated at 13,790,000 gallons. This is the smallest crop of record except for 1940 when 13,360,000 gallons were produced. Last year's production was 20,270,000 gallons and the 10-year average production is 21,113,000 gallons.

This year's low production results mainly from a 28 percent decrease in harvested acreage from last year. Acreage used for sirup production in Louisiana this year is only slightly more than one-third of that used for sirup in 1947. Yield per acre is less than last year in all producing States excent Alabama and Mississippi,

Only 7,625,000 gallons of sorgo sirun were produced during 1948. This was the lowest production of record and compares with 9,845,000 gallons in 1947 and the average of 11,437,000 gallons.

Slackened demand for sorgo sirup resulted in only 110,000 acres being harvested for sirup in 1948; this is the lowest of record. This year's low production may he attributed entirely to this smaller acreage because the yield per acre was considerably above both 1947 and the average Wather conditions were generally favorable throughout the season,

MAPLF PRODUCTS: This year 1,445,000 gallons of maple sirup were produced. This was only 71 percent of last year's production. Maple sugar production at 229,000 bounds was the lowest on record. Sixty-five percent of the maple sugar was produced by Vermont. Vermont was also the principal producer of sirup with New York second. Together these 2 States accounted for 73 percent of the total production. A large part of the Mew England sirup was dark colored.

Continuously warm weather during most of the tapping season held back the run of sap. The number of trees tapped was down about six percent from 1947 with some operators not tapping trees because of high labor cost. The sugar content of the sap was below average in many areas.

CROP REPORT
as of
December 1948

CROP REPORTING BOARD

Washington, D. C., December 17, 1948 3:00 P.M. (E.S.T.)

DRY BEANS: The 1948 dry bean crop of 20.833,000 bags of 100 pounds each (uncleaned) is the second largest of record, being exceeded only by the 1943 crop of 21 million bags. Current production may be compared with the 1947 crop of 17.2 million bags and the 10-year average of 16.7 million bags. The yield per acre of 1,087 pounds is the highest of record and compares with 979 pounds in 1947 and the 10-year average of 914 pounds per acre. The Nation's total planted acreage of dry beans was 1,971,000 acres, an increase of 7 percent over the 1,839,000 acres planted in 1947. The crop was planted about the usual date and under favorable conditions. Abandonment was comparatively light as the crop developed normally throughout the growing season and practically all the beans matured before frost. Harvested acreage is estimated at 1,917,000 acres, compared with 1,759,000 acres harvested in 1947 and the 10-year average of 1,832,000 acres. The 1948 crop was harvested under favorable weather conditions and there were fewer off-color and shriveled

California again ranked first in the production of beans, contributing approximately 26 percent of the U.S. total. Other ranking States include Michigan, Idaho, Colorado and New York.

beans than usual. Quality of the crop is comparatively high.

In the production of beans by commercial classes (cleaned) Pea and Medium Whites regained first place with a production of 4,476,000 bags, compared with 3,074,000 bags in 1947. Great Northern production totaled 4,127,000 bags, while last year only 3,576,000 bags were produced. The All White production, excluding Limas, accounted for approximately 49 percent of the total U.S. crop. In the colored varieties, Pintos continue in first place with a production of 3,105,000 bags -- down slightly from the 1947 crop of 3,241,000 bags. Other colored varieties show rather sharp increases in production this year, compared with a year earlier. In Michigan, where most of the pea or "Navy" beans are produced, the 1948 crop of 4,077,000 bags is up sharply from the below-average crop of 2,735,000 bags produced in 1947. New York, the main producing State for Red Kidneys, also shows an increase in production this year, compared to the 1947 crop. Nebraska's large crop took over first place in the production of Great Northerns. Idaho usually has been the ranking State in production of this variety. Colorado produced over 66 percent of the total Pinto crop. Production of 1,144,000 bags of Standard Lima beans in California is up from the 855,000 bags produced last year, but the production of 384,000 bags of Baby Limas is down from the 1947 crop of 1,058,000 bags.

PRY PEAS: Production in 1948 is estimated at a little less than 3.6 million 100-pound bags (uncleaned), equivalent to 3.265,000 bags of clean peas. The 1947 crop was a little over 6.5 million bags, equivalent to 5.970,000 bags of clean peas. Production this year is only about one-third as large as the record production in 1943. During the war years production ranged from 6 to 11 million bags, while before the war production generally ranged from 2 to 3 million bags.

The principal cause of the reduced production was a reversion back to about pre-war acreage. The acreage harvested is estimated at 292,000, which is 44 percent less than last year's acreage and 29 percent less than average. For the country as a warple, farmers intended to plant 470,000 acres this year, but due to a very wet. cool spring in the principal producing areas of Idaho and Washington they planted only 309,000 acres.

Even though the crop was planted late, with some loss from hail, and from wind while the crop was in the windrow, the yield per harvested acre this year was 1.221 pounds, only 2 percent less than last year and 1 percent less than average.

CROP REPORT as of December 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, Dig. C. December 17, 1948 3:00 P.M. (E.S.T. AND THE RESERVE OF THE PROPERTY OF THE PROPERT

About two-thirds of this year's production was of the Alaskan and other smooth green varieties, while about one-eighth was Canadas and similar kinds, and a little over one-fifth was other varieties.

These estimates do not include Austrian winter peas or cowpeas, but do not include peas grown for gorden seed as well as for food and feed.

SOYBEANS: The 1948 soybean crop is estimated at 220,201,000 bushels -- the largest of record. This is the second time soybean production has exceeded 200 million bushels, the first being in 1946 when the crop totalled 201 million bushels. Last year production amounted to 183.6 million bushels while the 1937-46 average is only 134.6 million cushels. The record production was brought about by exceptional. ty high yields since the acreage harvested for beans was about 8 percent less than a year ago. The U.S. yield of 21.4 bushels per acre is also an all time high. exceeding the previous record of 20.9 bushels per acre in 1939. Last year the yield was relatively low, 16.4 bushels, compared with the average of 18.8 bushels per acre.

The 11.7 million acres of soybeans planted alone for all purposes in 1948 was about 10 percent less than last year. The acreage interplanted with other crops, grown mostly in the Southern States, was also lower than a year ago -- 1,4 million acres, compared with 1.5 million acres in 1947. The interplanted acreage has been declining steadily for 10 years and has now reached the lowest level since 1935. An exceptionally high percentage of the total soyoean acreage was harvested for beans this year, about 83 percent for beans, compared to 82 percent in 1947. In the major producing North Central States, about 95 percent of the total acreage planted was harvested for beans, leaving only 5 percent for may and other purposes.

The 1948 season was very favorable for soybeans. Most of the acreage was planted at about the optimum time. The growing and the harvesting seasons were also unusually favorable. Frosts caused practically no damage to the crop. Harvesting was delayed in some areas, especially in the Eastern States. Occause of wet weather. but no serious damage resulted. Combining was largely completed by December 1 in the major producing areas. The quality of the crop is very good with many of the beans having an unusually low moisture content.

The North Central States alone produced more than 200 million bushels of soybeans, all but about 20 million bushels of the U.S. total. The high production in this area was brought about by a bumper yield of 22.0 bushels per acre. The same area last year had a yield of only 16.6 busnels per acre. All of the States of the area had yields above average except Wisconsin, where soybeans have been declining in popularity for several years. Illinois, the largest producing State, had the highest yield per acre -- 24.0 bushels, compared with only 18.5 in 1947. Iowa, the second largest producing State, likewise had the second highest yield --23 bushels per acre.

The South Atlantic States as a group had slightly lower yields than in 1947. North Carolina, the largest producing State of the area, had an exceptional year in 1947 with near record yields, but this year the crop was damaged by a dry period early in the season and a wet period in early October. The 13.5 bushel yield this year is one and one-half bushels less than in 1947.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CRUP REPORTING BOARD

Washington, D. C., December 17, 1948 Oecember 1948

The South Central States had record yields in several States and a very high yield of 18.8 bushels per acre for the area. This is far above the 13.9 bushels per acre produced in 1947. Each State of the area shows gains in production, with Arkansus reporting the largest increase. Froduction in Kentucky, Tennessee and Mississippi also registered sharp gains over 1947.

COMPRANS: Production of covpeas harvested as dry compeas is estimated at 3,416,000, bushels. This is less than the 3,466,000 bushels produced last year and, with the exception of 1946, is the lowest production on record. Only 1.6 million acres of cowpeas were planted for all purposes in 1948 -- the smallest acreage in the 25 years of record. This continues the formula trand which began in 1942. Although the acreage this year is just a little less than in 1947, it is only 38 percent of the 10-year average. The decline in cowpea acreage has been due largely to less planting for soil improvement purposes and to the substitution of other hay crops such as lespedeza and soybeans. Most cowpeas are picked by hand labor which has resulted in relatively high priced seed. This also has tended to hold down plantings.

The 1948 season was nearly ideal for cowpeas from planting time through harvest over much of the producing area. The yield of cowpeas harvested as dry cowpeas was 6.4 bushels per acre, the highest yield since 1931. Last year yield was 5.9 bushels while the 10-year average is only 5.3 bushels per acre. Yields in all major producing States were about average and above last year, except in Texas, where the 1947 yields were exceptionally high.

A record production of 2,268 million pounds of peanuts for picking and PERNUITS threshing is estimated for this year. This is 75 million pounds above previous record of 2,193 million pounds in 1942, and is the seventh consecutive year exceeding 2 billion pounds. The 3,214,000 acres harvested for picking and threshing is 8 percent smaller than the record total of 3,492,000 acres in 1943 and 5 percent below the acreage barvested in 1947. The reduction in acreage is more than offset, however, by the relatively high average yield per acre of 706 pounds, which is considerably above the yield in any year since the wartime expansion of acreage. Very good yields were realized in the Virginia-Carolina and Southeastern Areas, but extreme heat and drought reduced yields in the Southwestern Area. The total acreage of peanuts grown for all purposes, including acreage hogged off, micked and threshed and other utilization is estimated at 4,096,000 acres - a reduction of about 6 percent: from the total in 1947. In the Virginia-North Carolina Area, too much sain in the early season delayed planting, but open weather throughout most of the growing season was quite favorable and a large crop was made. Acreage, yield per acre and production in Virginia were the highest of record. The total production in this area of 585 million pounds, is about 17 percent above last year, andhas been exceeded only by the record crop of 588 million pounds produced in 1940. Conditions were mostly favorable for harvesting and curing. Picking started about 10 days earlier than usual, but was intertupted by frequent rains through most of November.

Growing and harvesting conditions also were favorable in the Southeastern areas and threshing of the crop was well along before being interupted by Nov-

CROP REPORT as of December 1948 · 3

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 5:00 I.M. (E.S.T.

ember rains. Total production for the area, at 1,245 million pounds, exceeds last years! large crop by 83 million pounds, and is second only to the record total of 1,324 million pounds produced in the area in 1943.

The Southwestern area had another discouraging season of low yields as the result of droughty conditions throughout most of the season. The early crop in South Texas was particularly poor. North Texas areas also were affected by drought, but conditions there were more spotted with some localities producing good yields. An unusually large acreage of late planted peanuts in South Texas benefited by good fall moisture conditions. Yields in Oklahoma were fair. Total production for the Southwestern area is estimated at 438 million bounds, compared with 519 million pounds in 1947.

VELVET BEANS: Acreage and production of velvet beans in 1948 drewed to the lowest level in the 25 years for which estimates are available. Production is estimated at 350,000 tons, about 14 percent less than the 407,000 tons produced last year and down almost two-thirds from the record production of 977,000 tons in 1940.

Velvet beans, grown entirely in the States of the deen South, have been declining in popularity for several years. Only 821,000 acres were grown in 1948, compared with slightly over a million a year ago and the average of 1,885,000 acres. Georgia alone had over one-half million acres in 1948 or about 62 percent of the U. S. total. Florida had about 150,000 acres, while the remaining acroage was concentrated in the Southern sections of South Carolina, Alabama, Mississippi, and Louisiana. The yield per acre of volvet beans this year was generally good, 853 pounds compared with only 786 pounds last year and the 10-year average of 813 bounds ber acre.

BROOMCORN: The 1948 broomcorn crop, estimated at 29,500 tons of brush, is the second smallest cron on record. This tonnage is 14 percent smaller than the 34,400 tons produced in 1947, and compares with the 1937-46 average of 42,690 tons. The four other years on record in which broomcorn production was near this year's low level were 1934 when only 23,700 tons were produced, 1939 and 1933 with 30,000 tons each, and 1925 with 31,000 tons, of the six commercial broomcorn States for which estimates are made, larger crops than in 1947 are shown for New Mexico, Colorado, and Kansas, while smaller crops are estimated for Texas, Oklahoma and Illinois.

The 1948 production of 29,500 tons as now estimated is 3 percent above the November estimate mainly due to increases in Texas, Kansas, and Oklahoma. The estimate for 1947 has been revised to 34,400 tons on the basis of carlot and truck movement, and other data.

The total planted acreage of 213,500 acres was 15 percent scaller than the 251,500 acres planted in 1947. Some acreage which would ordinarily be planted to broomcorn was diverted to other spring-planted crops requiring les labor. Soon after planting, the crop encountered more than the usual hazards. Frosts in March killed early plantings in Texas, and made it necessary to replant much of the acreage. Poor germination of seed in Colorado, and floods, rains, and winds in Kansas and Oklahoma hit the crop in the various stages of development.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:00 P.M.(E.S.T.)

tand made replanting necessary in many cases. Droughts plagued the early crop in the western area until August rains brought relief. As a result of these and other factors, 24,000 acres of 11.2 percent of the planted acreage was not harvested. The heaviest abandonment was in Texas, New Mexico, and Oklahoma. In 1947 a total of 19,000 acres or 7.6 percent of the blanted acreage was abandoned. For the six commercial States, the 1948 harvested acreage is estimated at 189,500 acres. This compares with 232,500 acres harvested in 1947, and the average of 276,000 acres.

Yields per acre were larger this year than last in four of the six States. In Texas the yield was only about three-fifths as large, while in Oklahoma this year's yield was equal to last year. For the six States, the average yield of 312 pounds per acre is 17 pounds larger than in 1947, and compares with the 1937-46 average of 308 pounds. The quality of the 1948 crop is generally good except for some brush which was overripe in Colorado, and some which was damaged by winds just prior to harvest in Oklahoma.

COTTON: The 1948 cotton crop is estimated at 14,937,000 bales, based on information as of December 1. This is the largest crop since 1957 and the seventh largest on record. It compares with the 1947 production of 11,857,000 bales and the 10-year average of 12,014,000 bales. The record crop was 18,946,000 bales produced in 1937.

The 1948 lint yield per acre, computed at 311.5 pounds, is the highest on record and compares with the 1947 yield of 267.3 pounds, and the 10-year average of 254.2 pounds. The previous all time high was 298.9 pounds produced in 1944. The unusually high yield this season is due, not only to exceptionally favorable weather, but also to increased use of fertilizer, and a larger proportion of the cotton acreage being planted in heavy-yielding areas. Record high lint yields are indicated in Virginia, Florida, Alabama, Mississippi, Arkansas, and Louisiana, with near record yields in many other States. California ic the only State with an indicated yield less than the 10-year average.

The acroage in cultivation on July 1 is estimated at 23,372,000 acres and compares with 21,500,000 in 1947 and 23,274,000 acres for the 1937-46 average. Abandonment this year is indicated at 1.6 percent, leaving 23,003,000 acres for harvest. This is 8 percent more than the 1947 harvested acreage. Compared with 1947, the indicated acreage for harvest this year is up 51 percent in California, 41 percent in New Mexico, and 22 percent in Arizona and Missouri. In Arkansas and Louisiana the acreage is up 14 and 12 percent respectively. Slight to moderate increases are indicated in all other States with the exception of Oklahoma where a decrease of 8 percent is estimated.

In California, weather at planting time was unfavorable and considerable replanting was necessary. Unfavorable weather continued through mid-June and by that time the crop was about three wocks later than average. In Northwestern Texas, dry soils delayed planting. In all other areas west of the Mississippi River the crop was planted under favorable conditions. In States east of the Mississippi River weather at planting time was generally favorable.

Hot dry weather in June and early July was very favorable for holding boil weevils in check. Soil moisture, however, was adequate for growth and fruiting and the crop made excellent progress. Continued dry weather in Texas

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:00 P.M. (E.S.T.)

with daily maximum temperatures of 100 degrees or more during most of August reduced crop prospects. In other areas high temperatures and less-than average rainfall hastened maturity of the crop and continued to limit boll weevil damage.

Harvest weather through October was exceptionally favorable and picking and ginning progressed at a satisfactory rate. In Texas, Oklahoma, and the far western cotton States, weather continued favorable through November. In the central cotton States, however, November weather was very unfavorable for harvesting the crop. With considerable cotton in the field, particularly in areas of heavy production, excessive rains and local floods caused some loss of open cotton and a marked reduction in quality of that remaining unpicked. As a result of the unfavorable weather prospective production declined during November. Part of the drop was due to the fact that in many areas reporters anticipated that more of the crop than usual would be left unharvested. Under the law the Crop Reporting Board is required to forecast total ginnings rather than total production.

For the United States, about 87.7 percent of the crowns ginned prior to December 1 compared with 86.9 percent for 1947 and 00.6 percent for the 10-year average.

. No estimate of cottonseed production for 1948 will be made until final ginnings for the season are released in May, 1949. However, if the ratio of lint to cottonseed is the same as the average for the past five years, -roduction would be 6,036,000 tons, compared with 4,681,000 tons in 1947 and the 10-year average of 4,947,000 tons.

HAY: Adequate supplies of hay were produced in 1948. The total of 99.8 million tons is the smallest since 1941 and 3 million tons less than the 1947 production. Although the 1948 crop is relatively small, compared with those of recent years, the supply (including carryover) in relation to the number of hayconsuming animals is near record and appears to be sufficient for most needs. Due to the rather sharp decline in clover-timothy hay and the generally favorable serson for alfalfa hay, the latter kind makes up a larger proportion of the total production then last year. Alfalfa makes up slightly more than one-third with 34 million tons; clover-timothy slightly less than alfalfa at 29 and one-third million tons; wild hay, over 12.8 million tons; lespedeza more than 7 and one-half million tons; soybean, cowper, and peanut hay 3 and one-third million; grain hay a little less than 3 million; and miscellaneous kinds nearly 10 million tons.

The total acreage of crops utilized for hay in 1948 is 2.5 percent less than last year. Moderate acreage increases develoed for alfalfa, wild and lespedeza hay, but were not sufficient to offset the relatively sharp decrease shown by clover-timothy. Hay was harvested from 73.6 million acres this year, 1.9 million less than last year, but about one-half million more than average. Part of this relatively large reduction from last year was undoubtedly due to farmers plowing up meadows this year, which they intended to plow up last year, but could not because of the wet spring in 1947. The average yield per acre, at 1.36 tons, is the same as last year and slightly above average.

The growing season was generally favorable for hay, except for excessive early season rains in the Northeast, which interfered with harvest and curing of hay, and a dry summer in the Corn Belt and Great Flains States, which reduced late hay yields. In general, harvesting was accomplished under more favorable curing conditions than last year, resulting in better quality hav.

CROP REPORT

CROP REPORTING BOARD

Washington, D. C.,

December 17, 1948

3:00 F.M. (E.S.T.)

ALFALFA: Alfalfa acreage harvested for hay in 1948, at 15 million acres, is only 168,00 acres more than last year, with most of the increase in the North Central and South Atlantic regions. Western States, with the exception of Colorado, have the same or smaller acreages than last year, as some alfalfa fields were utilized for seed instead of lay because of favorable seed prices and prospects of adequate hay supplies. In most Eastern States, the 1948 alfalfa hay acreage is as large or larger than a year ago. Severe summer drouth reduced yields in Kentucky and Tennessee. The yield for the United States was slightly above last year and well above average, resulting in a total production of 34 million tons. In general, quality was good as cuttings were made during favorable curing conditions.

CLOVER-TIMOTHY: Clover-timothy hay in 1948, at nearly 22 million acres, is 6.6

percent below last year and only slightly above the 10-year average. Sharpest reductions occurred in Corn Belt States where farmers plowed up old fields that ordinarily would have been broken up a year earlier had weather conditions been more favorable. Also, some fields intended for hay were pastured due to poor pasture conditions, and some winter damaged meadows were diverted to other crops. Yields were reduced materially in Wisconsin, Iowa, Minnesota, Kentucky and Tennessee as the result of dry weather. Yields per acre averaged about the same as last year in the North Atlantic and Western regions, much better in the South Atlantic region and much less in the South Central and the important North Central regions. Total production, at 29 and one-third million tons, is about 11 percent below last year but about 2 and one-half percent above the 10-year average production.

WILD HAY: Wild hay acreage harvested in 1948 is about 1 percent above last year with all of the increase occuring in the North Central region, mainly in Wisconsin, South Fakota and Nebraska. The increase in these States was due largely to dry weather, which reduced all hay prospects and increased the need for additional wild hay to fulfill hay requirements. Quality was generally good, as hay was cured under favorable conditions. Yield per acre in the North Central region was below last year, resulting in a total production of 12.8 million tons for the United States, a decrease of 4.7 percent from 1947.

OTHER HAYS: The acreage of lespedeza hay is 2.3 percent above last year, with Missouri, Illinois, Virginia and South Carolina shoving increases that more than offset rather sharp decreases in Tennessee, Kentucky and Kansas. The remainder of the lespedeza hay producing States had relatively small changes from last year. The average yield for the United States at 1.14 tons is sharply above last year and well above the 10-year average. Total production of 7.6 million tons is 13.2 percent above 1947.

Favorable grain prices caused a rather sharp reduction in acreage of grain crops cut for hay, especially in States in the Western region. Yields in all regions were about the same as last year, except in the South Atlantic and Western regions where significant increases resulted in an increase for the United States. However, total production is almost 3 percent below last year, due to the rather large decrease in acreage harvested. Soybean hay production is 4 percent below last year with slightly less than 1,2 million acres harvested, a reduction of 162,000 acres from 1947.

HAY SEEDS: Production of the six major seed crops--alfalfa, red clover, alsike clover, sweetclover, lespedeza, and timothy--in 1948, totaling nearly 481.8 million pounds, is 6 percent larger than in 1947 and 1 percent above the 1937-46 average. The larger 1948 crops of red clover, alsike clover, and lespedeza seed than in 1947 and also than the 10-year average more than offset

CROP REPORT as of December 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 December 1948 3:00 P.M. (E.S.T.)

the smaller (below average) crops of alfalfa, sweetclover, and timothy. Production of lespedeza, alfalfa, red clover, and sweetclover seed turned out 1 to 10 percent larger than was forecast, while the alsike-clover seed crop is a little smaller and the timothy-seed crop is much smaller than was forecast. Current supplies (production plus carry-over) of these seeds are 2 percent-larger than a year earlier, but 7 percent below the 1942-46 average.

It is estimated that 3,879,100 acres of the six major seed crops were harvested in 1948, compared with 3,864,200 acres in 1947 and the 10-year average of 4,199,650 acres. The 1948 acreage was above last year and also above average for red clover, alsike clover, and lespedeza, but below in those comparisons for alfalfa, sweetclover, and timothy.

The 1948 yields per acre of three seeds--red clover, sweetclover, and lespedeza -exceed those of 1947, while yields of the other three are smaller than in 1947. Compared with the average, yields of only red clover and timothy are below average.

Harvesting of the 1948 crops of these seeds began at about the usual time, but averaged about 4 days earlier than in 1947. Weather was favorable for harvesting most of these crops. The farm movement of each of the six seeds, except alsike clover, has been faster than in 1947, but compared with the average, the movement of three has been slover while that of three others has been faster. information regarding these six seeds and also Sudan grass and redtop seed follows.

ALFALFA SEED: The 1948 crop of alfalfa seed, estimated at 989,900 bushels of thresher-run seed, is the smallest crop since 1942. It is only 58 percent of the near-record 1947 crop of 1,700,000 bushels and 79 percent of the 1937-46 average of 1,259,920 bushels. The 1948 production is below that of 1947 in all producing States except four in the far West-Idaho, Wyoming, Utah, and Washington. The small production of alfalfa seed this year was due to unfavorable weather for seed production, heavier infestation of grasshoppers than usual, local shortage and high prices of hay, and relatively low prices received by growers for the 1947 crop of seed.

Decline from the average production is greater in the Northern States than in the Central States, but decline from last year is much greater in the Central States. Although the 1948 production in the Southern States is slightly above average, it is only about half as large as in 1947. Froduction by groups of States this year, last year, and the 10-year average is estimated as follows: Northern, 411,100 bushels in 1948, 557,000 bushels in 1947, and the average of 592,390 bushels; Central, 337,000 in 1948, 691,000 in 1947, and the average of 437,930; and Southern, 241,800 in 1948, 452,000 in 1947, and the average of 229,600.

The 1948 acreage of alfalfa seed in the United States is estimated at 614,100 acres, compared with 995,700 acres in 1947 and the average of 854,280 acres. Yield per acre is expected to average 1.61 bushels, compared with 1.71 bushels in 1947 and the average of 1.49 bushels.

RED CLOVER SEED: With larger acreages of red-clover seed than in 1947 reported in 12 out of 18 producing States and with a yield per acre only a little below average, production this year is indicated to be 41 percent

CROP REPORT as of Tecember 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 3:00 Р.М. (E.S.T.)

larger than in 1947 and 12 percent above average. The 1948 crop is estimated at 1,773,900 bushels, compared with 1,261,800 bushels in 1947 and the average of . 1.578.390 bushels. The largest increases over 1947 are in Michigan, Ohio, New York, and Indiana,

An estimated 1,830,500 acres were harvested this year, compared with 1,393,500 acres in 1947 and the average of 1,645,920 acres. High prices and a very good demand for red-clover seed in recent years were mainly responsible for the large acreage harvested for seed this year. The estimated 1948 yield of .97 bushel per acre compares with .91 bushel in 1947 and the average of 1.04 bushels.

The 1948 crop of alsike-clover seed is estimated at 388,400 ALSIKE-CLOVER SEED: bushels. This is 4 percent larger than the 375,200 bushels in 1947 and 20 percent larger than the average of 324,960 bushels. The increase over last year is due to the larger acreage harvested, which more than offsets the smaller yield per acre this year. Largest increases over the 1947 production are reported for Ohio, Indiana, and Wisconsin.

Acreage harvested for seed this year is estimated at 139,800 acres, compared with 128,300 acres in 1947 and the average of 139,460 acres. A yield of 2.78 bushels per acré is indicated this year, compared with 2.92 bushels in 1947 and the average of 2.37 bushels.

SWELTCLOVER SEED: On the second smallest acreage of sweetclover seed on record, production this year is 7 percent below the very small 1947 crop and 38 percent below average. The 1948 production is estimated at 533,200 bushels, compared with 574,300 bushels in 1947 and the average of 853,180 bushels.

Sharpest reductions from last year's production occurred in Ohio, Indiana, Illinois, and Kansas.

An estimated 188,200 acres were harvested this year, compared with 216,700 acres in 1947 and the average of 325.080 acres. Loss of popularity of sweetclover as a soil-building crop in some sections and the low prices of this seed compared with prices of competing crops were chiefly responsible for the small acreage harvested for seed this year. The 1948 yield per sore is indicated at 2.83 bushels, compared with the 1947 and average yield of 2,65 bushels.

LESPEDEZA SEED: Production of lespedeza seed this year, estimated at 241,560,000 pounds, is the second largest crop ever harvested. It exceeds by 61 percent the 1947 production of 149,760,000 nounds and by 44 percent the average of 167,695,000 bounds. The marked increases over the 1947 and average crops are due both to larger acreages and yields in most States. The weather in nearly all producing sections, except notally Tennessee and Kentucky, was favorable for the production of this seed,

An estimated 974,800 acres were harvested this year, compared with 732,500 acres in 1947 and the average of 809,080 acres. A record yield of 248 pounds per acre is indicated this year, compared with 204 pounds in 1947 and the average of 205 pounds.

TIMOTHY SEED: The 1948 crop of timothy seed is second smallest on record. It is estimated at 423,800 bushels, only 27 percent of the 1947 production of 1,589,400 bushels and 28 percent of the average of 1,524,760 bushels, but 59 percent larger than the record small crop of 266,800 bushels in 1934.

ORCP REPORT as of Docember 1948

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 17, 1948 3:00 p. M. (F. y. T.

Acreage harvested for seed was smaller than last year and than usual in each of the producing States. It is estimated that 131,700 acres were harvested this year, compared with 397,400 acres in 1947 and the average of 125,830 acres. The indicated yield of 3,22 bushels per acre this year compares with 4 bushels in 1947 and the average of 3.56 bushels.

SUDAN-GRASS SEED: Production of Sudan-grass seed this year, estimated at 23,800,000 pounds of clean seed, is 10 percent larger than the small 194v crop of 21,540,000 pounds, but less than half the 10-year average production of 49,763,000 pounds. Production in 6 out of 8 States is larger this year than last. but production in 6 is below average.

. An estimated 58,700 acres were harvested this year, compared with 56,700 acres in 1947 and the average of 137,806 acres. The small acreare in recent years is due chiefly to the poor demand for this seed. Yield per acre this year, well above average, is indicated at 405 pounds, compared with 380 pounds in 1947 and the average of 350 pounds.

REDTOP SEED: The 1948 crop of redtop seed fell much below expertation mainly because of heavy rains at harvest time. It is estimated at 5,300,000 pounds of clean seed, smallest crop on record, and compares with 15,300,000 pounds in 1947 and the average of 17,290,000 pounds.

An estimated 96,000 acres were harvested, which is less than half the 1947 acreage of 202,000 acres and only 37 percent of the average of 256,400 acres. A very favorable planting season for soyberas and corn this year, and prospects for better cash returns for these crops than for redtop seed influenced many former growers of redtop seed to plow up their redtop meadows. Yield per acre is indicated at 55 pounds of clean seed, compared with 76 pounds in 1947 and the average of 67 pounds.

Oklahoma produced 15,400,000 pounds of mung beans this year, compared with 10,080,000 pounds in 1947. This year's crop was the second largest of record for the State-the record being 24,200,000 pounds in 1945. Weather was generally favorable for beans produced on wheat stubble, but dry weather during August and September resulted in fairly heavy acreage losses in late producing areas. The yield per acre was the second highest in the short history of the crop, elthough only 280 pounds per acre this year, compared with the record yield of 540 rounds produced in 1942. Oklahoma growers planted 70,000 seres and harvested 55,000 acres this year. There are reported to be large stocks of mung beans both on farms and in warehouses. Early Decem er prices were such that many growers were holding their crops on farms, with indications that many growers may use large quantities for livestock feed unless market conditions become more favorable before the next crop season,

^{1/} Acreage partially duplicated.

Asparagus, snap beans, lima beans, beets, cabbage, sweet corn, cucumbers, peas, pimientos, spinach, and tomatoes.

Artichokes, asparagus, snap beans, lima beans, beets, cabbage, cantaloups, (including honeydews, honeyballs, and miscellaneous melons), carrots, cauliflower, celery, cucumbers, eggplant, lettuce, onions, peas, peppers, spinach, tomatoes, and watermelons grown commercially for market. Excludes farm gardens and most market gardens.

Totals are for crops shown in preceding columns, omitting alfalfa seed, red clover seed, alsike clover seed, and lespedeza seed. These are included in the count of crops, but the acreage is not included because mostly duplicated in the hay acreage; the acreage of peanut hay, largely duplicated in peanuts picked and threshed, has been deducted. Other crops not included are sweet corn for market, some of the less important commercial vegetables (70,100) acres in 1948, farm gardens, most market gardens, hops, spelt, hemp, velvetbeans, various legumes and other crops harvested by livestock, minor crops, and fruits and muts. The acreages shown include some crops harvested in succession from the same land.

^{5/} Preceding column plus estimates of acreages planted, and not harvested, as shown in separate table of acreage losses.

1/The	acreages	shown for	winter	wheat re	nresent	the acres	sown in	the pred	ceding	fall and	not har-

1/The acreages shown for winter wheat represent the acres sown in the preceding fall and not harvested, thus including considerable land subsequently planted to other crops. The acreages shown for cotton include more than 10 million acres plowed under in 1933. The totals do not show total crop losses chiefly because of the large acreage of hay land which produced nothing except pasturage in some dry seasons. 2/Rice, buckwheat, potatoes, sweetpotatoes, sugar beets, and dry field peas. 3/Excludes grains cut for hay.

7/ For some Ctatas in sout :		. 1.2							

^{1/} For some States in certain years, production includes some quantities unharvested on account of economic conditions. In 1945, 1946, 1947, and 1948 estimates of such quantities were as follows (tons): 1945-Plums, California, 1,000; Prunes, Western Oregon, 9,700, 1946-Prunes, Western Oregon, 4,200; 1947-Prunes, Western Oregon, 3,500; 1948-Prunes, Idaho, 3,000; Eastern Washington, 600; Western Oregon, 12,000; California, 7,000 (Dry basis). These quantities are not included in utilization figures.

^{2/} Includes 2,000 tons harvested but not utilized because of abnormal cullage.

3/ The drying ratio in Calif., is about 2 lb. of fresh fruit to l lb. dried; in Wash. and Ore., from 3 to 4 fresh to l dried. 4/ Revised. 5/ Excludes quantities used on farms where grown.

6/ Includes small quantities frozen in some years prior to 1941. 7/ Short-time average. 8/ Dry basis.

1/ Season begins with the bloom of the year shown and ends with the completion of harvest the following year. In California picking usually extends from about Oct. 1 to Dec. 31 of the following year. In other States the season begins about Oct. 1 and ends in early summer, except for Florida limes, harvest of which usually starts about April 1. Estimates of production include fruit consumed on farms, sold locally, and used for manufacturing purposes, as well as that shipped. Fruit ripened on the trees but destroyed by freezing or storms prior to picking is not included. For some States in certain years, production also includes some quantities donated to charity, unharvested, and /or not utilized on account of economic conditions. In 1946 and 1947, estimates of such quantities were as follows (1,000 boxes): 1946, Calif, Navel & Misc. oranges - 485; Valencias, 454; grapefruit, Desert Valleys - 13; Fla. Early & Midseason oranges-900 tangerines -800; grapefruit, seedless -800; other, 1,800; Texas grapefruit, Desert Valleys - 16; Fla. tangerines -600; grapefruit, seedless -2,400; other, 1,300; Texas grapefruit - 2,300; Ariz. Navel and Miscellaneous oranges -6; grapefruit -944. 2/ The indicated production for 1948 is based on reported prospects on December 1. 3/ Includes small quantities of tangerines, 4/ Net content of box varies. In Calif. and Arizona the approximate average for oranges is 771b. and grapefruit 65 lb. in the Desert Valleys: 68 lb. for California grapefruit in other areas; in Florida and other States, oranges, including tangerines, 90 lb. and grapefruit 80 lb.; California lemons. 79 lb.; Florida limes, 80 lb. 5/ In California and Arizona, Navels & Miscellaneous.
